**Surgical Treatment of Kidney Pelvis.**—Abrahamsen reviews twenty cases of hydronephrosis in which treatment was administered in the last three years and reports the five cases of plastic surgery of the pelvis and transplantation of the ureter. Ureteropyelostomy, he says, may be considered when exhaustion calls for rapid and lenient intervention. In his first case of plastic surgery nephrostomy was not done, in spite of infection of the pelvis before operation, and complications set in, necessitating nephrectomy; in the other four cases the post-operative course was uneventful. He advises conservative operation in relatively young patients in good condition, with no or slight infection, with perhaps bilateral renal disturbance and likewise, in case of simultaneous mechanical obstacle, to passage of the urine. If large aberrant vessels are seen on operation, compression of the vessels is recommended, to determine whether the blood supply to the pole of the kidney is compromised, in which event ureter transplantation is indicated. The author says that infections of the more banal kind tend to occur in a double kidney, usually in its lower portion, and describes a case of double kidney with pyuria and coluria in which cystoscopy and roentgen examination failed to reveal the cause, diagnosis being made after pyelography. Heminephrectomy with removal of the dilated ureter was followed by recovery; on examination, a year later, the patient was well. A case is also reported in which pyelotomy disclosed a membranous pyelitis and nephrotomy was done, with good results.

## FACTORS OF RESISTANCE IN EXPERIMENTAL POLIOMYELITIS

WITH COMMENTS ON IMMUNITY IN POLIOMYELITIS

EDWIN H. LENNETTE, Ph.D.

AND

FRANCIS B. GORDON, Ph.D.  
CHICAGO

The question of immunity in acute anterior poliomyelitis has remained a challenging problem in virus studies. Investigations conducted since the early work of Landsteiner and Popper and of Flexner and his associates have attempted to solve the difficult situation, but experimental medicine has not as yet placed in the hands of the clinician and public health official effective tools capable of preventing or specifically treating this condition. Attempts to devise methods of immunization have been too numerous to recount, but generally the procedures have not been sufficiently effective and safe in the experimental disease for proper application to man. The noncultivability of the infectious agent on lifeless mediums and the availability of only a single, expensive experimental animal have been practical deterrents, but the basic difficulties have been more recently appreciated; namely, the peculiar pathogenesis of the disease and specifically the tendency of the virus to follow neural pathways. Efforts to induce an immunity in man have been based on classic principles effective in other infectious states, and insufficient attention has been paid to the basic difficulties and to factors of the host's resistance to this particular virus.

For the past five years we have carried on an experimental study of the factors concerned in resistance to and pathogenesis of poliomyelitis in *Macaca mulatta* (*Macacus rhesus*). An analysis and correlation of the observations have led to an evaluation of certain elements that are concerned in immunity to experimental poliomyelitis. The value of such observations with respect to the human disease depends on whether the factors operative in the disease of monkeys may validly be applied to the condition in man. On the basis of these analytic studies and ancillary observations we have attempted to explain the observed facts in terms of immunity in poliomyelitis.

A reconstruction of our experimental procedures allows a logical consideration of possible factors of resistance under the following headings: the naso-

pharyngeal mucosa, the intestinal mucosa, the spleen as a large depot of reticulo-endothelial cells, the demonstrable antibodies in the blood serum, certain bodily physiologic factors, the relationship between the blood and the central nervous system, and the rôle of the olfactory tract. In such a survey the external barriers, certain anatomic and physiologic elements, and some essential relationships of the nervous system are considered.

### EXPERIMENTAL

*The Nasopharyngeal Mucosa.*—The epidemiology of poliomyelitis points to the nasopharynx as the common portal of entry of the virus. Experimental evidence for this was on hand as early as 1910, when Flexner and Lewis<sup>1</sup> showed that monkeys could be infected by applying the virus to this region. Later reports by various workers have emphasized the significance of the olfactory nerve endings in the nasal mucosa as the probable anatomic structures by which the virus enters the body. There appears, however, to be some resistance offered by the mucosal barrier in monkeys, since even relatively large and repeated doses of virus are not always effective in infecting animals. This is further borne out by the observation by Schultz and Gebhardt<sup>2</sup> that a preliminary flushing of the nasopharynx with acid phosphate solution reduces the resistance to virus administered intranasally.

This observation we have confirmed by noting that, without the previous washing with acid phosphate, we obtained poliomyelitis in sixteen of twenty-four monkeys, whereas all of nine monkeys succumbed to the disease after we adopted the technic of washing with the acid solution, and in fact with the use of less amounts of virus than previously. (These animals do not include those in which some other experimental factor was introduced.)

Clearly, the monkey's nasal mucosa offers a barrier of resistance to infection, possibly by the presence of mucus overlying the terminal hairs of the olfactory nerves. The action of the acid phosphate presumably is to digest the mucus and to flush the mucosa. The presence of an alterable barrier in this site is further indicated by the finding of Armstrong and Harrison<sup>3</sup> and of Sabin, Olitsky and Cox<sup>4</sup> that the effect of alum applied to monkeys' nasopharyngeal mucosa is to increase the resistance of the animal to virus given by this route.

The experimental work was supported by grants from the International Committee for the Study of Infantile Paralysis and from the Rockefeller Foundation to the University of Chicago.

*The Intestinal Mucosa.*—The gastro-intestinal tract has been suspected on epidemiologic grounds of being the route of infection in man. Positive experimental results have been obtained only when some extreme measure was resorted to, and then not regularly. Lennette and Hudson<sup>5</sup> and Flexner<sup>6</sup> have recently reviewed the situation and reported their failures to elicit any experimental support for gastro-intestinal infection. We<sup>5</sup> attempted to infect monkeys by administering large amounts of virus to isolated intestinal loops, thus bringing the virus to mucosa presumably normal physiologically and devoid of the effect of dilution by intestinal contents. Our experiments were entirely negative, which may be explicable on the basis of lack of exposure of unmyelinated nerve fibers in the intestinal mucosa or for the reason that regions of intestine optimal for virus invasion were not used. From these experiments it appears that in the monkey the intestinal mucosa is a distinct barrier to infection.

*The Spleen.*—Much work has been done to show the rôle of the spleen in infectious processes. It is not our intention to review here the evidence bearing on the activity of the organ as a large accumulation of reticulo-endothelial cells. That this system is active in the disposal of infectious agents and is probably an important factor in immunity is now generally recognized.

Whether the spleen could be a factor of resistance in experimental poliomyelitis depends in large part on whether the virus circulates in the blood vascular system. This has seldom been demonstrated in the experimental animal and for that reason we did not at first attempt to gain information on the immunologic activity of the spleen following intranasal or intracerebral inoculation. Furthermore, either of these methods of inoculation is so effective that a large series of animals would be necessary to gain reliable data on the susceptibility effect of removing the spleen. On the other hand, intravenous inoculation of virus is effective only when large doses are administered, and by employing a sub-infective dose any lowered resistance obtained by splenectomy might be apparent. The present summary of experimentation by Lennette<sup>7</sup> is concerned chiefly with the effect of removal of the spleen before and after intravenous injection of virus.

When large amounts of virus were given intravenously to normal animal controls, half the monkeys (nine of eighteen) became infected, while the same proportion of monkeys (four of nine) died of poliomyelitis that were similarly injected after healed splenectomy. Of fourteen immunized and convalescent animals without spleens, none succumbed to the same treatment. When smaller doses of virus, however, were administered to six normal monkeys as controls, none showed any reaction, whereas two of five monkeys previously splenectomized had the specific infection. This was the only evidence that splenectomy played any part in lowering the resistance of the experimental animal to intravenously injected virus. A further examination of the rôle of the spleen was made by removing it from one to five days after inoculation of virus intravenously. None of six monkeys so treated became infected by doses of virus subinfective for normal (intact) animals.

The question of whether the spleen takes up the virus after intravenous inoculation was approached by test-

ing for virus in spleens removed one, three and five days after vascular injection of nonparalyzing doses. Twelve monkeys (six normal, three convalescent and three immunized), each group distributed as to time of splenectomy, were operated on. The virus was recovered from the spleens of only the two normal animals splenectomized twenty-four hours after virus injection.

This rapid disappearance of the virus in active form in the spleen was again demonstrated by its recovery from the spleen only one day (two monkeys) and not three and five days (two monkeys each time) after intrasplenic injection of potent virus. Is the virus, under these conditions, destroyed by phagocytosis or neutralized by antibodies?

An explanation was sought by examining the spleens of monkeys in an acute stage of poliomyelitis following cerebral inoculation of virus. The virus was not demonstrated in three spleens not perfused but was detected in extracts of perfused spleens of two other monkeys examined. Apparently, the spleen contained the virus, whether intravenously or cerebrally inoculated, and the virus was not recoverable later than twenty-four hours after vascular injection because of some other factor, possibly the neutralizing effect of antibodies. This hypothesis was tested by first examining splenic extracts of immune and normal monkeys for a neutralizing property; both of two spleens of the former neutralized virus, whereas neither of two of the latter had a neutralizing effect. This property associated with immune spleens was, however, apparently dependent on the contained blood of the spleen, since the neutralizing property was not demonstrable in the tissue of perfused spleens from three animals dying of poliomyelitis, three immune monkeys and three normal controls. We do not overlook, however, the possibility of there being too little tissue antibodies to be experimentally demonstrable.

It thus appears, under the conditions of these experiments, that there is some reason to consider the spleen as a factor of resistance in experimental poliomyelitis, even though minor. Splenectomy previous to intravenous virus seemed to lower the resistance to infection in a certain proportion of animals. The virus was taken up by the spleen in some way but rapidly disappeared as active virus, whether by its intracellular destruction or neutralization by antibodies. Perfusion of spleens removed the neutralizing property, which indicates its absence or small amount in splenic cells and makes uncertain the site of antibody formation in experimental poliomyelitis.

*Circulating Antibodies.*—The neutralizing antibody is the only form of immune body demonstrable in poliomyelitis. Its significance is debatable. Jungeblut and Engle<sup>8</sup> propose that it may be considered, under certain circumstances, as nonspecific. It has not regularly been demonstrated in the serum of persons convalescent from poliomyelitis; Kolmer and Rule<sup>9</sup> have recently summarized such observations. Furthermore, the neutralizing property is not always present in the serum of immune or convalescent monkeys. The experience of various workers in this regard has been brought together by Gordon.<sup>10</sup>

10. Gordon, F. B.: Active and Passive Immunity in Experimental Poliomyelitis, to be published.

We (Hudson and Lennette<sup>11</sup>) have been unable to find any experimental evidence that alters our point of view that the neutralization test in man and monkey is a specific antigen-antibody reaction. We agree, however, that it may not always be demonstrable in the presence of an immunity that has been called tissue resistance.

On the other hand, experimental work by Gordon<sup>10</sup> leads us to propose that its presence in monkey serum is not evidence that an effective resistance to infection exists in that animal. Gordon has "vaccinated" twenty monkeys with various preparations and found twelve of nineteen of them (one test animal died of an intercurrent infection) to have a serum neutralizing property. When virus was instilled intranasally, however, eighteen of the twenty animals died of poliomyelitis, and a nineteenth succumbed following a subsequent intracerebral inoculation. One concedes that the test of resistance was experimentally severe, but the intranasal route may be adjudged more natural and less severe than the traumatizing cerebral method of inoculation. Evidently, the mere presence of a serum neutralizing property in the monkey cannot be considered as direct evidence of complete resistance to intranasal infection. The explanation probably lies in the pathogenesis of the disease, in that an extreme measure of immunization is necessary to protect the nerve cells against virus invasion. An immunization that leads solely to the production of antibodies may not be sufficiently intensive to confer an effective protection on the cells essentially parasitized.

*Physiologic Factors of Menstruation and Maturation.*—The immunity enjoyed by an individual to a certain infectious disease is entirely understandable when it follows recovery from a recognizable attack. Difficulties are met, however, in attempting to explain the resistance shown when no specific definable experience has been observed. Direct evidence is at hand in some cases, such as diphtheria, indicating that inapparent attacks account for much of one's resistance to specific disease. This may be the case in poliomyelitis; but, in the absence of a cultivable infectious agent, it is difficult to identify all the steps in the process of immunization. Aycok<sup>12</sup> uses the term "autarcesis" to explain the inapparent bases of resistance, and he correlates such a condition with the physiologic state as influenced by environmental factors. Jungeblut and Engle<sup>13</sup> propose that variations in the susceptibility to poliomyelitis can be traced to physiologic alterations attendant on such factors as maturation of the individual and changes in endocrine activity. They present experimental evidence to indicate that menstruation as an endocrine function and maturation as a physiologic development both lead to resistance to infection and to the presence of nonspecific neutralizing antibodies in the serum.

The hypothesis of the influence of menstruation has been tested by Hudson, Lennette and King,<sup>14</sup> who found that artificial menstruation induced in ten young monkeys by injections of anterior pituitary extracts failed

to lead to a development of neutralizing serum antibodies or to a demonstrable resistance in the nine animals injected with virus. Similarly, we<sup>11</sup> were unable to detect antibodies in thirty-one serum samples from fifteen adult males and six adult females (one specimen gave a positive test once and a negative test later). Criteria for the adulthood of these animals were as follows: The dentition of the animals was either early permanent (four monkeys) or completely permanent (seventeen monkeys); the testes were fully descended or menstruation had been observed over long periods; the heights were from 63 to 84 cm. and the weights were from 3.2 to 11 Kg. In these experiments we did not find evidence supporting the view that menstruation as such and sexual maturation are factors in the resistance to experimental poliomyelitis.

The problem of the conditions that influence resistance and susceptibility to infectious disease is of extreme importance and should be approached from as many angles as is experimentally possible. It is entirely conceivable that endocrine functions influence the outcome of exposure of the host to the parasite, but before such can be accepted in poliomyelitis, the experimental evidence should be consistent and continuous.

*The Blood-Central Nervous System Relationship.*—We have presented evidence bearing on the parts played in the defense to experimental poliomyelitis by the nasopharyngeal and intestinal mucosa, the spleen, humoral antibodies and certain physiologic factors. What of the central nervous system itself and its relation to the remainder of the experimental animal?

The attention is called to the nervous system in poliomyelitis by the essential pathologic condition therein and by the experimental work from 1912 to 1934 (reviewed by Lennette and Hudson<sup>15</sup>) that first incriminated the olfactory tracts and then proved the neural pathway of the virus from the nasal mucosa to the spinal cord. We<sup>15</sup> confirmed the observation of other workers that sectioning the olfactory tracts in the monkey prevented infection after intranasal instillation of virus. A further experience was recorded of being unable to infect the same five animals by massive intravenous doses, whereas four of five monkeys with intact olfactory tracts succumbed to the same intravenous dosages. This apparently essential rôle of the nerve pathways under these conditions was made more significant by our recovery of the virus from nasopharyngeal washings pooled from a group of three normal monkeys fatally infected with intravenous virus.

These experiments emphasize the selectivity of the virus for nervous tissue and suggest, without proving, a mode of infection after intravenous administration of virus. To circumscribe this relation between the virus and the nervous system, Lennette and Hudson<sup>16</sup> explored the possibility of the effectiveness of the blood-central nervous system barrier as a factor of resistance to vascular virus. A sublethal dosage of virus by this route was established and then, borrowing the technic of cerebral damage by sterile starch injections from the yellow fever work by Sawyer and Lloyd,<sup>17</sup> we were able to break the blood-central nervous system

barrier and obtain fatal infections with virus given intravenously. Three normal monkeys so treated died of poliomyelitis, while six controls without starch in the brain showed no reaction. Apparently, the cortical injection of sterile starch permitted the intravascular virus to enter the damaged nerve cells from the capillaries and the disease progressed therefrom. It is impossible to say whether the damage to the nerve cells or the break in the blood capillaries is the more important factor.

This principle of damage allowing the parasitization of nerve cells was disclosed further when, by the mere cutting of certain large peripheral nerve trunks, fatal infections were induced by immediate intravenous administration of amounts of virus previously found sublethal to normal animals. The femoral nerve was cut in three monkeys, the sciatic in two and the vagus in two; poliomyelitis developed in one monkey with a cut femoral nerve and in one in which the vagus was sectioned.

To summarize, it appears that the nervous system is the essential site for the pathogenesis of poliomyelitis virus invasion, that the olfactory tract is an important route of entry to the body, and that there is a distinct barrier between the vascular and nervous systems, which can be broken by mechanical means. Thus the distinctness of the central nervous system from the remainder of the body in the pathogenesis of experimental poliomyelitis becomes even more apparent.

#### COMMENT

A conception of the mechanism of immunity in poliomyelitis is based on the direct and indirect types of evidence furnished by the accumulated knowledge of the epidemiology, pathology and pathogenesis of poliomyelitis, and the nature of the virus and the experimental disease. It would be tiresome to the reader, if not well-nigh impossible, to make satisfactory and just reference to all the work that has added with a steady crescendo to our acquaintance with this condition. The availability of the monkey as an experimental animal has allowed a finer perception of the factors in immunity not only through the analysis of factors of resistance in the experimental condition but also in the study of the disease as it exists in the natural host.

We conceive of acute anterior poliomyelitis as being transmitted from person to person most commonly by droplet infection. It is not sufficient to rely on acute cases as sources of virus, and the rôle of carriers and missed cases is indicated not only by the evidence of epidemiologists but also by the work of experimentalists (Kramer<sup>18</sup> and others). Once the virus has reached the individual, it may lodge in the nasopharynx or tonsils or enter by the gastro-intestinal route. We believe that the latter route is not likely, although we recognize the weight of certain epidemiologic evidence. Whether the virus increases in its mucosal nidus in the upper respiratory region is not known. Multiplication in this site would result in its maintenance in the population by offsetting the effect of dilution by transfer. Increase in the enclosed central nervous system in acute and subacute cases does not wholly account for the prevalence and distribution of the virus in man,

unless a recontamination of the nasal mucosa by exuded virus is hypothecated in such individuals. We<sup>19</sup> have reported finding the virus in this region after intravenous injection of large amounts of virus, amounts probably not present in the vascular system in the natural infection. Burnet,<sup>19</sup> on the basis of experiments with the louping-ill virus in rats, proposes that that virus may be discharged onto the mucosa from the parasitized olfactory cells. Elucidation of the problem of nasopharyngeal residence of the poliomyelitis virus awaits further experimentation.

The next step in the immunologic process is the absorption of the virus from the mucosal surface. Evidence that others and we have presented points clearly to the exposed nerve endings of unmyelinated nerve fibers as the route of entry of the virus into the body. The first cranial nerve represents such a portal, the parasitization of which leads to the virus invasion of the central nervous system. The factors that determine the absolute or relative degree of invasion begin with the condition of the upper respiratory tract, as detailed under the consideration of the mucosal barrier, and perhaps as obtains in the pathologic state (e. g., tonsillectomy).

Once the virus has entered nervous tissue, its migration seems to continue along axonal pathways, passing from the olfactory tract through the hypothalamus, thalamus and medulla to the cord. The evidence for this sequence was reviewed by Faber.<sup>20</sup> The significant point is that the virus has been traced in nerve cells. While such information is taken from studies on acute infections, there is no reason to doubt its occurrence in subacute and nonclinical experience with the virus. A question concerning immunity is whether the virus remains restricted to the cells of the nervous tissue. If it does, a tissue resistance, of a type not now understood, may account for the relative insusceptibility had by those who have experienced an exposure of their nervous tissue to virus; if it is not restricted, and this we are inclined to accept, the more extensive effects of immunity may become manifest, with antibodies appearing in the blood serum in addition to tissue resistance. The factors that control the outcome of a primary exposure to virus are not definable but probably include those vague forces that are operative in determining the parasite-host balance in infections in general. One significant factor may well be the amount of virus that an individual acquires or possibly cultivates on his mucosa. Once it has penetrated the nerve cells, however, the undefined forces referred to seem to exert an influence. Considering the epidemiology of poliomyelitis, the duration of immunity may depend on the result of the original exposure or on the repetition of exposure.

As discussed in the general experimental section, neutralizing antibodies in the serum of man and monkeys seem to be specific in nature. If this is true, evidence must be looked for that the virus leaves the nerve cells and acts as an antigen, stimulating the antibody-producing cells of the body. Experimental evidence confirms this not only in the occasional finding of virus in the blood stream during experimental infection but also in our demonstrating the virus in the spleens of monkeys cerebrally inoculated. These obser-

vations indicate the probable mode of antigenic sensitization of extraneural tissue and would account for the presence of serum antibodies.

The conception that the body is immunized by virus that migrates perhaps variably from its intraneural site allows for the irregularity of antibody content in the serum. Furthermore, an explanation for the observation that sometimes the virucidal content of serum of persons without an acute attack is higher than of those convalescent from this disease may lie in the possibility that the former are more effective in their antibody response while the latter are less efficient in this regard, are more susceptible and on recovery have responded with a lower serum antibody content.<sup>21</sup> To postulate this, however, one must consider that the serum property is an indication of neural overflow of virus and hence is but a mark of exposure of body tissue to the antigen. Its occasional absence in the blood of human convalescents and its very infrequent lack, as observed by us, in the serum of monkeys convalescent from acute attacks support the idea of tissue resistance without extraneural migration of the virus.

We have been unable in our experiments to determine the site of antibody formation. Some experimental evidence we have offered tends to show that, once the virus has left the axonal pathways, the spleen may play a rôle in resistance. Because of the difficulties in this type of experimentation with the poliomyelitis virus, however, too much emphasis should not be placed on this evidence. Nevertheless, because of the interpretive significance of antibodies, we propose that cells and parts outside the central nervous system contribute to manifestations of immunity in poliomyelitis. This gains support in the claims of clinicians that patients react as to a generalized infection, and of pathologists who have described changes in the lymphoid system in fatal cases.<sup>22</sup>

The possibility arises that antibodies result from a vascular distribution of the virus from the upper respiratory tract. This is conceivable and is not incompatible with the neural migration of virus, since we have shown how virus intravenously injected was recovered from the nasopharynx of monkeys and did not cause disease in animals so injected whose olfactory tracts were sectioned. If the virus primarily becomes intravascular, it appears that the migration by the olfactory tracts is the probable secondary route, in view of our experiments on the barrier between the vascular and central nervous systems. The primary vascular invasion would explain much in immunity and would be acceptable if it were not for the necessity of granting the neural route from the nasopharynx, in which case the direct migration by this pathway may better be considered in the natural droplet infection of poliomyelitis.

Much experimental work has been done on the problem of artificial immunization. Gordon<sup>10</sup> dealt with this by injections of virus adsorbed to alumina-gel and of virus purified by adsorption to and elution from the same gel. His experience was that, in the attempt to immunize, fatal infections occasionally occurred and that, even under these extreme circumstances, neutralizing antibodies were not always produced and almost

all monkeys surviving "vaccination" were still susceptible to virus administered intranasally. As others have found,<sup>23</sup> amounts of potent virus too near the lethal limit were necessary for the production of immune bodies in the serum. The failure to build up a resistance to the virus in nerve cells finds its explanation in the distinctiveness of the nervous system from the remainder of the body so far as the pathogenesis of the disease is concerned.

Schultz and Gebhardt<sup>24</sup> have expressed a similar point of view, especially in connection with the apparent inability of injected immune serum to reach and block the virus in its intracellular location in the nervous system. Correspondingly, artificial active immunization may be inadequate in furnishing protection by extraneural stimulation of antibodies. Abundant evidence is at hand, however, that proves "vaccination" possible, and we have accomplished it by intravenous injection of relatively large amounts of virus. The necessity of extreme measures for the production of an effective active immunity may be due to a barrier surrounding the central nervous system, similar to the blood-central nervous system barrier to intravenous virus. The penetration of this barrier by antibodies for the protection of the central nervous cells may be possible only when near-lethal amounts of active virus are used. The question naturally arises, therefore, as to the desirability of attempting active immunization of man under these circumstances, and further, whether serum antibodies induced by injection of virus are necessarily an indication of protection of the nerve cells to virus invasion.

As has been so often expressed by students of poliomyelitis, measures designed to produce both active and passive immunity must take into account the properties of the virus and the peculiar pathogenesis of the disease, and be directed toward the immunization of the cells of the central nervous system.

#### SUMMARY

Elements concerned in the resistance of the experimental animal *Macaca mulatta* to acute anterior poliomyelitis were investigated.

1. A certain degree of resistance was demonstrated in the nasopharyngeal mucosa, although ample evidence was found that pointed to the upper respiratory tract as the portal of entry of the virus. The intestinal mucosa was an effective barrier to infection by virus administered in isolated intestinal loops.

2. The rôle of the spleen as an organ involved in resistance was studied by the effect of its removal before and after the intravenous injection of virus. Splenectomy seemed to reduce the resistance in two of eleven monkeys and then only when the operation was done before virus injections. In other experiments, virus was found in the spleen in the first twenty-four hours after intravenous or intrasplenic injection. Its disposal in the spleen seemed to depend in part on the contained blood antibodies, since the virus was recovered from spleens of monkeys dying of poliomyelitis only when the organs were perfused. The site of antibody formation was not defined.

22. Poliomyelitis, International Committee for the Study of Infantile Paralysis, Baltimore, Williams & Wilkins Company, 1932, p. 169, 359.

3. Neutralizing antibodies were formed in monkeys "vaccinated" with certain preparations, but their presence was not an indication of effective protection of the animals to intranasal virus.

4. Natural or artificially induced menstruation and physiologic maturation of monkeys did not lead to the formation of a demonstrable virucidal property of the blood.

5. Sectioning of the olfactory tracts prevented infection not only after intranasal virus but also after injections of virus intravenously. The selectivity of the virus for this pathway to the nervous system was further indicated by the recovery of virus from the nasopharynx of other monkeys infected by the blood stream.

6. An explanation was found for the relative resistance imposed as a barrier to the virus between the vascular and central nervous systems. Sublethal doses were made fatally infective by damage to the cerebral cortex by starch injections, and to certain large peripheral nerve trunks by section.

These experiments may be interpreted as meaning that the poliomyelitic infection is primarily and largely of the central nervous system.

A theory of immunity in poliomyelitis logically develops from an analysis of pathogenesis and factors of resistance. We conceive of the virus of this disease as entering the body by the olfactory tract, migrating intracellularly through the central nervous system to the loci of predilection in the cord, and sensitizing the nervous tissue in some way so that it is resistant to reexposure to the virus. The virus apparently escapes from the nervous tissue and irregularly invades the body, exciting the defense mechanisms of the body with the stimulation of antibody formation. The neutralizing antibody in the natural condition is thus an indication of specific sensitization by extraneural stimulation after nerve cell migration of the virus. Antibodies induced by the artificial conditions so far devised are not necessarily a measure of nerve tissue resistance.

Artificial immunization of man, either active or passive, should take into account the distinctness of the central nervous system in the pathogenesis of poliomyelitis and the significance of certain factors of resistance. The interpretation of demonstrable antibodies should be made in the light of these observations, and measures of immunization may well be directed toward the neural features of the disease.

---

**Clever People and Quacks.**—I have noticed that clever people are usually fools about their own health. The nice clever people, those who have great gifts and an accompanying simplicity of soul, fall into the hands of charlatans and dishonest healers because, knowing nothing of objective pathology, they will accept any statement or treatment which the quack likes to suggest. . . . The difficult and rather worthless type is the successful, usually rich, person, who having differentiated himself from the common herd by the amassing of money, or the purchase of a title, must needs be individual in his therapeutic adventures. The common basis for the absolute and stupid faith which such a man exercises in respect to some new treatment is conceit, for he cannot bear to be as other men are and must always know better than the ordinary mortal. Examples of this stupidity, of this Athenian demand for some new thing, are so numerous that I will not attempt to chronicle them, but every practitioner probably hears of a case of this sort about once a month.—Howard, Christopher: *The Art of Medicine, Lancet* 1:754 (March 28) 1936.

## LOW BASAL METABOLIC RATE AND THE USE OF DESICCATED THYROID

JOHN M. BERKMAN, M.D.  
ROCHESTER, MINN.

While certain facts relative to the occurrence of low metabolic rates have been definitely established, there are other factors concerning which there is little conclusive knowledge. Although a low rate of metabolism is common to all the conditions under consideration in this paper, it is quite apparent that the causes of this low rate are different.

The basal metabolic rate is maintained in the organism in part by thyroxine, which acts in the tissues as a catalyst and, to some extent, regulates the rate of energy transformation. It is a known fact that in normal individuals approximately 40 per cent of the heat production, as measured by the consumption of oxygen, is controlled by the thyroid gland. When the thyroid gland is destroyed and the organism has had sufficient time to become free from thyroxine, the basal metabolic rate drops to from —40 to —45 per cent.

When in association with a known depletion in the body's supply of thyroxine the basal metabolic rate has dropped to —18 or —20 per cent, certain physical disturbances associated with the disease myxedema become apparent. The basal metabolic rate may, however, fall to much lower levels than this without the appearance of the characteristic physical changes of myxedema and without any apparent disturbance of the thyroid gland. Thus the question arises as to whether depression of the basal metabolic rate must of necessity be dependent on a deficiency of thyroxine. Although at present no positive answer can be given to this question, the evidence suggests that the thyroid gland is not involved, at least primarily, in all conditions associated with basal metabolic rates lower than the standard average normal.

That the thyroid gland plays only a small part, if any, in the production of a low basal metabolic rate in conditions other than myxedema is suggested by the fact that, in the treatment of myxedematous patients with desiccated thyroid, very obvious conditions both physical and otherwise are completely eradicated by such treatment, whereas, in the treatment of nonmyxedematous patients with low metabolic rates, desiccated thyroid is often required in much larger doses to maintain a normal basal metabolic rate, but it does not bring about any apparent physical change.

Any classification of conditions associated with a low metabolic rate must, then, take these facts into consideration, and a workable classification must ignore many highly important but unknown factors. A classification which satisfactorily separates conditions associated with a low rate of metabolism is given in the accompanying tabulation.

### MYXEDEMA

Myxedema is caused by either partial or complete destruction of the thyroid gland by extirpation, disease or a combination of the two. It may occur spontaneously as a result of a degenerative process, the cause of which, when known, usually is thyroiditis. It may also occur following thyroidectomy in cases in which the gland was previously affected by a degenerative process; in such cases the thyroid tissue remaining, although

under ordinary conditions adequate in size, does not produce sufficient thyroid secretion to prevent myxedema.

In true hypothyroidism it is known that, when the basal metabolic rate falls below —20 per cent, characteristic nonpitting edema is going to be present to some extent. Usually, if the disease is kept in mind, the characteristic appearance of swelling about the eyes and face, dryness of the skin and hair, and both mental and physical slowness lead to a correct diagnosis. These symptoms, together with the deliberate and thick speech, aching and stiffness of the joints, marked intolerance to cold, and the peculiar pallor so characteristic of the disease, usually direct one's attention to the diagnosis if one is familiar with the condition. Not infrequently hoarseness is the disturbing symptom that causes the patient to consult his physician.

The characteristic tendon reflex of myxedema which is so pathognomonic of the disease is one in which the contraction component is normal but the relaxation component is markedly slower than normal, at times being so slow as to appear to be absent. This sign is always best seen in the achilles tendon reflex; however, not infrequently it is present in all reflexes of the extremity.

In the usual textbook picture of myxedema, a marked gain in weight is given as the rule. However, many patients have not experienced a gain in weight and many patients with myxedema are thin. It is true, of course, that patients who are naturally somewhat obese have great difficulty in reducing their weight even on a near starvation diet. This fact is easily accounted for by the low rate of metabolism and the inactivity accompanying myxedema.

Myxedema is frequently accompanied by secondary anemia. This, associated with the macrocytosis, high color index and achlorhydria, frequently leads to a diagnosis of pernicious anemia, the characteristic clinical picture of myxedema having been disregarded. An increase in the anemia occurs shortly after beginning treatment with desiccated thyroid. This increase is relative rather than actual because, shortly after treatment has been started, the edema begins to disappear and the plasma volume becomes increased without effecting a change in the cellular content. Frequently the greater part of the edema disappears after the first few days of treatment when 3 or 4 grains (0.2 or 0.24 Gm.) of desiccated thyroid is used as the initial dose. During this stage of treatment it should be remembered that there is a tendency toward an increase in urea in the blood.

There are other interesting and unexplained features of the disease, some of which may be confusing. There is an increase in size of the heart shadow in the six-foot roentgenogram. This increase in size may not at first be apparent, because the heart may not be considered abnormally large for the patient's age. But often, when a roentgenogram taken before treatment was begun is compared with one taken after treatment has been given, enlargement of the heart is evident.

Three principal electrocardiographic changes are seen in cases of myxedema and these changes disappear after treatment. The change most frequently seen is flattening or inversion of the T waves. The second change, which occurs much less frequently, is prolongation of the PR interval, which persists after administration of atropine. The third change is rare and consists of definite prolongation of the QRS complex.

Menorrhagia is not an infrequent occurrence in cases of myxedema, and in the absence of primary pathologic conditions in the uterus it responds satisfactorily to treatment of myxedema.

The values for cholesterol in the blood are almost invariably definitely elevated. The significance of this has as yet not been satisfactorily explained.

During the treatment of myxedema and prior to the time that the basal metabolic rate approaches normal, much larger amounts of desiccated thyroid may be necessary to elevate the metabolic rate and to maintain it at an elevated level than later on. At times, after a normal basal metabolic level has been reached, it is surprising what a small amount of desiccated thyroid is necessary to maintain that level. This is probably best explained by a change in the absorption of desiccated thyroid. It would appear that, during the stages in the treatment in which the metabolic rate is so low, the desiccated thyroid administered is not so completely absorbed as it is when the metabolic rate has reached a normal level.

There is no disease known that it more satisfactory to treat than myxedema.

#### LOW BASAL METABOLIC RATE WITHOUT MYXEDEMA

Since 1917, H. S. Plummer has recognized a group of cases in which the basal metabolic rate is below the average normal level but in which edema and some of the other characteristics of myxedema do not develop. This group comprises a much larger number of cases than any of the others mentioned. The characteristics of myxedema do not develop in these cases although the basal metabolic rate may fall much lower than —20 per cent, and deafness, slowness of recovery of the peripheral reflexes, hoarseness, slowness of mental and physical reactions, slowness of speech, and electrocardiographic changes do not occur except in the presence of coincidental disease.

Patients have the sallow complexion so characteristic of a low metabolic rate. The skin is usually dry, but there is much less tendency to scaling than in cases of myxedema. Fatigue is probably the most common and frequently the most prominent symptom. Gastric acidity is frequently low and achlorhydria is common. The values for cholesterol in the blood, although frequently higher than normal, are not as a rule as high as in cases of myxedema. The majority of these patients are asthenic and their complaints are of a functional nature, resembling those of neurasthenic patients. The symptoms and complaints coincide closely with those of the usual exhaustion syndrome. There seems to be a familial tendency in these cases to a lower than normal basal metabolic rate. In all probability the low basal metabolic rate has been present long before the patient is seen, or it had always been present. Therefore, the evidence is not sufficient to state that in this group of cases the lowered rate of metabolism is directly responsible, even in part, for the illness of which the patient complains.

In this group of cases there are subgroups in which certain symptoms are so predominant as to make them principal complaints. The symptoms otherwise correspond in general to those of asthenia.

*Menstrual Disturbances.*—Because of the comparative infrequency with which menstrual disturbances are associated with a low basal metabolic rate, and because of the occurrence of menstrual disturbances in the absence of the latter, one is not warranted in consider-

ing a low basal metabolic rate as necessarily being an abnormality. It is probably in such cases an individual characteristic.

The disturbances of menstrual flow associated with a low metabolic rate are amenorrhea, oligomenorrhea, and menorrhagia. Mussey and Haines<sup>1</sup> gave a group of patients who had amenorrhea, oligomenorrhea, or menorrhagia and a low basal metabolic rate carefully regulated doses of desiccated thyroid by mouth. In order to determine the effectiveness of giving desiccated thyroid alone in such cases, no other form of treatment was used. Haines and Mussey found that definite improvement was obtained in 72 per cent of the cases in which patients had amenorrhea, in 55 per cent of those in which patients had oligomenorrhea, and in 73 per cent of those in which patients had menorrhagia. They also found that aside from whether or not there was improvement in menstrual function, about 75 per cent of the entire group of patients reported improvement in their general health after elevation of their basal metabolic rates to within average normal limits.

#### Conditions Associated with a Low Metabolic Rate

1. Myxedema: A definite clinical entity associated with positive physical signs, including nontapping edema, and a basal metabolic rate of —20 per cent or lower.
2. Low basal metabolic rate without myxedema: A large group of cases that includes several subgroups. These may be classified in accordance with various physiologic disturbances which are not of necessity associated with any physical characteristics. The low basal metabolic rate may be a familial characteristic and it is often associated with asthenia. A low basal metabolic rate without myxedema may be associated with:
  - (a) Menstrual disturbances.
  - (b) Sterility.
  - (c) Hypersecretory rhinitis.
3. Anorexia nervosa: Loosely associated with a combination of psychical and physical signs. It may or may not be associated with a low basal metabolic rate. It was previously within normal limits.
4. Hypopituitarism: A definite clinical entity, associated with characteristic physical signs, but without edema, regardless of the basal metabolic rate.

**Sterility.**—Cases are sometimes encountered in which, although intolerance to cold and fatigability have been bothersome symptoms, sterility has occasioned the examination of the patient. In certain of these cases, conception has occurred following the finding of a low basal metabolic rate and its elevation by the use of desiccated thyroid.

**Hypersecretory Rhinitis.**—This third subgroup comprises cases in which patients complain chiefly of obstruction of the nasal passages. In these cases the mucous membrane of the nasal passages appears edematous, as in vasomotor rhinitis; however, the wet appearance noted in cases of vasomotor rhinitis is not present. Hypersecretory rhinitis is occasionally recognized as being associated with a low basal metabolic rate. At times there is satisfactory local response to elevation of the basal metabolic rate by administration of desiccated thyroid.

#### ANOREXIA NERVOSA

Anorexia nervosa is a term applied to a group of symptoms resulting from psychic disturbance and from starvation, the characteristics of the clinical picture being so constant as to warrant its acceptance as a definite clinical entity. The sequence of events appears to be as follows: A psychic disturbance develops which

is directly responsible for, and is followed by, loss of appetite. The resulting lessened intake of food finally leads to inanition, which in turn brings about a low rate of metabolism. This decrease in the metabolic rate has a tendency to depress the appetite still further because less nourishment is required to maintain body weight when the metabolic rate is low than when normal or high. In this manner a vicious circle is set up. Most of the loss of weight occurs early in the course of the disease, and at a certain point the weight becomes more or less stationary. It appears that depression of the basal metabolic rate in such cases acts somewhat as a protective mechanism, for, if the metabolic rate should remain normal, death would undoubtedly occur rapidly. The fact that the favorable results which have been observed have occurred after considerable time, though the metabolic rate and intake of food had maintained near normal, suggests that other secondary degenerative processes have taken place as a result of inanition.

In cases of low basal metabolic rate caused by hypothyroidism, the clinical features of the condition appear following depression of the metabolic rate. In anorexia nervosa it seems that the opposite occurs; that is, the low basal metabolic rate follows, rather than precedes, the appearance of clinical evidence of the condition. Although patients with anorexia nervosa are to some degree intolerant to cold and may have dry and dry skin, they do not have the facial edema characteristic of myxedema. Many of them, however, have metabolic rates lower than those frequently found in cases of marked myxedema. In cases of true hypothyroidism in which the basal metabolic rate is less than —20 per cent, facial edema is present; this has not been true in any of the cases of anorexia nervosa seen at the clinic. Consequently, in these cases the lowered metabolic rate has not been considered to be attributable to primary hypothyroidism.

Between the years 1917 and 1930 a diagnosis of anorexia nervosa was made at the clinic in 117 cases which would indicate that the condition is not so common as one might expect. Although the condition is not limited to younger individuals, a majority of the patients were between the ages of 18 and 35 years. Eighty-nine of the 117 patients were females, and it is interesting to note that 53 per cent of these females had amenorrhea. Menorrhagia did not occur. The basal metabolic rates of the majority of the patients ranged from —20 to —42 per cent.

As to the appearance of these patients, two striking characteristics attract one's attention at first glance: extreme emaciation and the rather marked pallor. The pallor is attributable to the low basal metabolic rate and not to the anemia, as is shown by the fact that in the entire group of 117 patients, none had an erythrocyte count of less than 4,000,000 per cubic millimeter. The patients appear preoccupied, but when questioned they respond quickly. Their general attitude seems to be one of apathy.

The two principal complaints are (1) loss of appetite and of weight and strength, and (2) various gastrointestinal disturbances, which do not correspond to the conditions found in any of the well known gastrointestinal diseases. These gastro-intestinal symptoms which consist mostly of gas, distress, fulness and pain, are exaggerated immediately after meals and occur in the epigastrium.

Benedict and others have shown by observation of professional fasters that even in the less severe degrees

1. Mussey, R. D., and Haines, S. F.: Amenorrhea and Oligomenorrhea Associated with Low Basal Metabolic Rates, *Am. J. Obst. & Gynec.* 27: 404-407 (March) 1934.

of undernutrition in healthy individuals depression of the basal metabolic rate occurs.' This was accompanied also by a fall in the systolic blood pressure.

While the treatment in some cases of anorexia nervosa is very satisfactory, this is far from being the rule, and there are several factors such as insufficient funds and inability to cooperate which may make the problem of treatment difficult. Response to treatment occasionally is so satisfactory, however, that one feels warranted in attempting it in all cases, even though the patient's refusal to cooperate may appear to make such treatment worthless from the start. Reestablishment of a normal intake of calories is the direct goal, and to this end treatment with a preparation of thyroid gland has been proved to be a valuable adjunctive measure.

#### HYPOPITUITARISM

Pituitary insufficiency is very frequently associated with a subnormal basal metabolic rate. The chromophobe type of tumor of the anterior lobe of the pituitary gland is by far the most frequent cause of hypopituitarism. Cushing and Davidoff<sup>2</sup> reviewed 107 cases of histologically verified chromophobe adenoma of the pituitary gland and found the average basal metabolic rate to be -14 per cent. The rate was below -20 per cent in twenty-one of these 107 cases.

Patients suffering from hypopituitarism have a characteristic pallor, but it differs from that of myxedema in that it is waxy, the skin appearing as though it were thin and almost transparent. The skin rarely has a tendency to scale; also the facial edema which is constantly present in myxedema is lacking. The secondary anemia that is so often seen in association with myxedema is not present in cases of hypopituitarism.

Myxedematous patients frequently have alopecia, and at times there may be considerable loss of hair of the scalp. This is not the case in hypopituitarism. The cutaneous hair, especially of the face and pubis, is frequently absent in hypopituitarism, which is not the case in myxedema. This lack of facial hair and the characteristic pallor are frequently diagnostic when the patient is a man. In hypopituitarism, with the exception of the extremely rare case of Simmons' cachexia, there is usually some tendency to obesity. In the male such obesity tends to have the feminine characteristics such as are seen in the presence of a marked Fröhlich syndrome.

The symptoms of hypopituitarism may be purely general and of no diagnostic value; however, during routine general physical examination homonymous hemianopia may be roughly elicited. In such cases further and more conclusive evidence is obtained from examination of the perimetric fields and from roentgenologic examination of the sella turcica.

Simmons' cachexia, although rare, may present considerable difficulty in distinguishing it from anorexia nervosa; however, some of the differential features just mentioned may aid in diagnosis.

Usually, the general appearance of both myxedema and hypopituitarism suffice to make the differential diagnosis. Naturally, hypopituitarism does not involve the use of desiccated thyroid in treatment.

#### THE USE OF DESICCATED THYROID

There are two distinct indications for the use of desiccated thyroid in which its value has been definitely shown: (1) as a specific in the treatment of myxedema and (2) as a method of elevating a low basal metabolic

rate to normal in the absence of myxedema for the purpose of improving the general condition of the patient. Desiccated thyroid has been used extensively, regardless of patients' basal metabolic rates, both as a means of reducing weight and as an adjunct in connection with a weight reduction diet. It has also in some instances been used both preoperatively and postoperatively with the intention of speeding up the rate of the blood stream and so preventing postoperative venous thrombosis and pulmonary infarction. The limits of this paper, however, do not permit discussion of these two uses of desiccated thyroid.

In general it would appear that, either through lack of familiarity with the use of desiccated thyroid or with the conditions under which its use is indicated, the full effect of this substance has in many instances not been obtained. Patients are seen to whom desiccated thyroid has been given for short periods because of various conditions for which, from both a theoretical and practical standpoint, its use is not indicated. Equally often the estimation of a single basal metabolic rate has been the only criterion for the use of desiccated thyroid. In the absence of myxedema or of the symptoms of a low metabolic rate without myxedema, such as fatigue, intolerance to cold, and menstrual disturbances as described before, the use of desiccated thyroid is not indicated, even though the basal metabolic rate has repeatedly been found to be below the normal average for an apparently healthy individual. It should be remembered that in some instances a basal metabolic rate below the normal average is in all probability an individual characteristic.

Occasionally, desiccated thyroid is given without previous metabolic determinations, the pulse rate being followed frequently and this being considered to be indicative as to whether the dose should be increased or decreased. This method, in which the dose is of course entirely empirical, is not advisable and leads to unfavorable results.

There is apparently some misunderstanding also as to the time it takes for desiccated thyroid to produce an effect, as many patients have been told not to take it at night as it might cause insomnia. The action of desiccated thyroid is slow, and therefore to some extent cumulative; also, following the ingestion of desiccated thyroid a considerable period elapses before the effect of the drug has entirely disappeared. For clinical purposes one should wait a month before attempting to determine an individual's basal metabolic rate following the use of desiccated thyroid. It has been shown that, following cessation of the administration of thyroxine to myxedematous patients, the daily loss of thyroxine is approximately 6.5 per cent of the quantity then present. A curve showing this reveals a rapid loss of thyroxine at first, the loss becoming increasingly slower as time goes on. The most rapid disappearance of thyroxine occurs during the first two weeks, the rate of disappearance from then on becoming slower. At the end of a month, as stated before, the effect of either thyroxine or desiccated thyroid has for all practical purposes disappeared.

As a general rule one does not expect favorable results from elevation of the metabolic rate unless that rate is in the region of -16 per cent or lower and when such a rate is associated with definite symptoms, the most significant of which are fatigue and intolerance to cold.

As a routine, in the absence of nephritis and cardiovascular disease, an initial dose of 12 grains (0.8 Gm.) over a period of three or four days may be used, the

<sup>2</sup> Cushing, Harvey, and Davidoff, L. M. Studies in Acromegaly: IV. The Basal Metabolism, Arch. Int. Med 39: 673-697 (May) 1927.

dose being the same each day. At the end of that time a metabolic determination is made. Assuming that the original metabolic rate was in the region of  $-20$  per cent, the rate of the majority of individuals will be elevated to a point between zero and  $-10$  per cent. A dose of either  $1\frac{1}{2}$  or 2 grains (0.1 or 0.13 Gm.) of desiccated thyroid is then given, and at the end of another four or five days the metabolic rate is again determined. Depending on the value of metabolic determinations at intervals of every four or five days, an individual dosage will be determined which will maintain the basal metabolic rate at from  $-3$  to  $-5$  per cent. It has been found that the general feeling of these patients is better when the metabolic rate is maintained at a level slightly below zero than above it. To maintain this level, in the majority of cases 1,  $1\frac{1}{2}$  or 2 grains of desiccated thyroid is required daily. In other cases, however, the dose needed may be more or less dependent on trial; in some instances it may be found that 1 grain daily, for either five or six days out of each week, will be required.

When the original metabolic rate was considerably lower than  $-20$  per cent, it may be found that after an interval of a few days following the initial dose of 12 grains a second course of 12 grains over a period of three or four days may be required to bring the metabolic rate above  $-10$  per cent. At times, especially in the presence of severe associated conditions such as chronic nephritis, coronary sclerosis and severe hypertension, extreme caution should be used in administering desiccated thyroid, small doses such as 1 or  $1\frac{1}{2}$  grains being used from the beginning of the treatment.

In determining the maintenance dosage, it must be remembered that each patient presents an individual problem. To be sure that the dosage is correct, further metabolic determinations should be made at the end of a period of two months.

As a rule the time consumed in elevating the metabolic rate and in determining the individual dosage of desiccated thyroid is from three to four weeks. It is very important, especially in the treatment of myxedema, to remember that during elevation of the metabolic rate there may be retention of urea. This, of course, indicates the use of smaller doses of thyroid extract; also in the treatment of myxedema it may be found that, although it may have been necessary to use a comparatively large total amount of desiccated thyroid to elevate the metabolic rate to the desired level, a daily dose of less than 1 grain (0.065 Gm.) will maintain that level. In the treatment of anorexia nervosa it is important that at least a normal caloric intake be maintained during and after elevation of the metabolic rate to prevent further loss of weight.

It seems advisable also to mention the occurrence of symptoms which are very characteristic of and accompany elevation of the metabolic rate. Patients complain of headache and generalized aching and pain in the muscles and bones. There is a loss of appetite and, at times, nausea. These symptoms usually appear during the second or third day and increase in intensity into the second week, during which they gradually decrease. At the end of three weeks, adjustment to the normal metabolic rate has taken place and such symptoms disappear.

In cases of myxedema, when 12 grains of desiccated thyroid is used as the initial dose, the facial edema begins to disappear on the second and third days and may to a great extent be gone by the sixth day. There may be continued improvement in the general condition over a period of two months or even longer.

It has been our practice at the clinic to adhere to the use of desiccated thyroid prepared by one company, as there is considerable variation in the potency of preparations of desiccated thyroid put out by different companies. While the doses given in this paper may not be found to agree with figures obtained in other instances, the relative dosage will be found to be comparable.

This method of elevating the basal metabolic rate may appear time consuming and unnecessarily detailed, but it has proved in our experience to be the most satisfactory method.

## ARTIFICIAL FEVER TREATMENT. OF CHOREA

### PRELIMINARY REPORT

CLARKE H. BARNACLE, M.D.

JACK R. EWALT, M.D.

AND

FRANKLIN G. EBAUGH, M.D.

DENVER

Since the installation of three Kettering hypertherms<sup>1</sup> in this clinic in February 1935 we have treated thirteen cases of Sydenham's chorea with artificial fever. Pyretotherapy has been so satisfactory that we wish to report the results at this time.

Sutton<sup>2</sup> in 1931 called attention to the treatment of chorea by the induction of fever with triple typhoid vaccine. Later reports by Sutton and Dodge<sup>3</sup> review the literature pertaining to fever therapy in the treatment of chorea and report satisfactory therapeutic results in 150 attacks of chorea with triple typhoid vaccine. They felt that it materially shortened the course of chorea, thus saving many hospital days. In 1935 these workers<sup>4</sup> continued their studies of fever therapy, using radiant energy in the treatment of rheumatic carditis. These workers conclude that "artificial fever therapy produced by intravenous injection of typhoid vaccine or radiant energy has no harmful effect on carditis in these children." Reports at the fifth annual fever convention at Dayton, Ohio,<sup>5</sup> indicate that "results with artificial fever treatment of twenty-eight cases of chorea have been excellent. Many cases were cured and the majority notably improved. Associated endocarditis was not a contraindication." Desjardins<sup>6</sup> reports the results at the Mayo Clinic, stating: "Nine children with chorea who have been treated have all improved satisfactorily but greater experience will be required to give us a correct perspective on the value of artificial fever in comparison with other methods of treatment." At this clinic we have initiated a long term study of artificial fever therapy of chorea.

From Fever Therapy Department, University of Colorado School of Medicine and Hospitals.

1. This apparatus was conceived and perfected at Miami Valley Hospital, Dayton, Ohio, and at the Research Laboratories of the Frigidaire Division of the General Motors Corporation, Dayton. We are indebted to Dr. Walter M. Simpson and Mr. Charles F. Kettering of the General Motors Company for the privilege of using the apparatus, three hypertherms being now in constant operation at this clinic.

## PROCEDURE

We are using the Kettering hypertherm,<sup>7</sup> an air conditioned cabinet, as a means of inducing artificial fever in the cases treated. In the treatment of the first few cases, fever sessions of two and one-half hours were given at intervals of from three to six days and at temperatures ranging from 103 to 106 F. (rectal). Experience has convinced us that the patients respond more rapidly if the two and one-half hour fever sessions are given daily at temperatures of from 105 to 106 F. (rectal). This procedure materially shortens the entire course of the chorea attack and quickly restores the patient to normal activity. It is our policy to insist on strict rest during the interval between treatments. Many of our cases were outpatients and were cared for in the home, while the more severe choreic cases required hospitalization. A cardiologist has carefully examined the cases with severe cardiac involvement and was consulted during the course of their treatment. The progress of the patient has been used as a guide to the amount of fever necessary.

## CASES

We have classified our chorea cases as mild, moderate and severe. Mild cases imply minimal choreiform movements of an extremity or muscle group with trivial functional incapacity. Those cases classified as moderate show gross choreiform movements of the extremities, trunk and face. These children are unable to perform coordinated acts. They are unable to speak coherently and cannot feed or dress themselves. Hypotonia is a marked symptom. In severe cases there is total incapacity. Attempts at voluntary movements result in violent choreiform movements. The patients cannot speak, there is a marked difficulty in deglutition, and hypotonia is severe.

CASE 1.—A boy, aged 13 years, was referred from the cardiac clinic and treated as an outpatient. Treatment was started March 28, 1935, one month after the onset of a moderate chorea. There had been no previous attacks. Examination revealed advanced rheumatic endocarditis. An electrocardiogram disclosed left axis deviation. He was given ten fever treatments, of two and one-half hours each, of from 103 to 104 F. (rectal), at intervals of from three to four days. Improvement, after the first treatment, was rapid and steady. There was no evidence of chorea after the sixth fever treatment (April 13), but the course of ten treatments was completed. There has been no recurrence to date. He has been followed in the cardiac clinic and is now restored to full activity.

CASE 2.—A youth, aged 16, was admitted to the hospital May 25, 1935, in his first attack of a very severe chorea. The onset occurred seven weeks prior to admission and was associated with acute rheumatic fever and endocarditis. Treatment consisted of eight fever sessions of two and one-half hours, at from 105 to 106 F. (rectal), given at from four to five day intervals. After the third treatment, choreiform movements were present only after excitement. The condition was so severe on admission that intravenous sodium amytal sedation was necessary to carry the patient through the first two sessions. He had recovered on July 3, and he has suffered no recurrences to date. Cardiac conditions were unchanged.

CASE 3.—A girl, aged 11 years, admitted to the hospital June 3, 1935, presented her first attack of a moderate chorea. The onset, six weeks prior to admission, followed an attack of acute rheumatic fever with endocarditis. Roentgen examination showed moderate enlargement of the heart. She was given eight sessions of fever, of two and one-half hours each, at from 105 to 106 F. (rectal), at intervals of from three to four days. Improvement was steady following the first treatment, and there

was no clinical evidence of chorea after the fifth session. A course of eight treatments was completed, July 11. Roentgen appearance of the heart was normal.

CASE 4.—A boy, aged 12 years, was admitted July 13, 1935, in a fulminating attack of severe chorea. There had been no previous attacks. The onset, two weeks before admission, followed an acute rheumatic fever associated with severe cardiac involvement. The heart was markedly enlarged to the left with pericardial effusion. Dyspnea was severe. He was given ten fever sessions of two and one-half hours each, at from 105 to 106 F. (rectal), at intervals of from three to four days. After the first session he was able to talk. After eight treatments (August 6), all evidence of choreiform movements had disappeared. However, at this time, following an infection of the upper respiratory tract, the pericardial effusion increased in amount. Two more treatments were given and the effusion subsided. Six months later examination of the chest revealed the heart to be of normal size without effusion. There has been no recurrence of chorea to date.

CASE 5.—A boy, aged 13 years, received as an outpatient July 9, 1935, suffered from moderate chorea. He had had no previous attacks. Examination revealed clinical evidence of rheumatic endocarditis with decompensation as evidenced by dyspnea, edema of the feet and ankles, and enlargement of the heart. He was given seven treatments of two and one-half hours each, at from 105 to 106 F. (rectal), at intervals of four days. There was no evidence of chorea after the fifth treatment, July 24. There has been no recurrence to date. The cardiac condition has steadily improved and the patient is now on a full activity program.

CASE 6.—A girl, aged 8½ years, admitted to the hospital Aug. 24, 1935, presented a first attack of acute, mild chorea. The onset occurred six days before admission, with no cardiac involvement. Treatment was started immediately. She received twenty-one sessions of fever of two and one-half hours each, at from 105 to 106 F. (rectal), at two to three day intervals. This case presented an unusual aspect in that the chorea became progressively more severe after the first eight treatments. However, following the total course of twenty-one sessions of fever, no choreiform movements were present. She was discharged October 23 as recovered, and there have been no recurrences to date. We have classified this case as severe.

CASE 7.—A boy, aged 11 years, admitted to the hospital Oct. 23, 1935, was suffering from his first attack of a moderate chorea. The onset three months before admission followed an acute attack of rheumatic fever associated with mitral stenosis with insufficiency. Prior to admission to this clinic he had been treated with a series of typhoid injections but had shown no response. Treatments consisted of eight sessions of fever of two and one-half hours each, at from 105 to 106 F. (rectal), given at intervals of from three to four days. He was discharged as cured, November 2. There has been no recurrence to date. The cardiac condition is unchanged.

CASE 8.—A girl, aged 5 years, was admitted Jan. 28, 1936, in her first attack of moderate chorea. The onset was associated with rheumatic fever and endocarditis two weeks prior to admission. Mild decompensation necessitated digitalis. Treatment consisted of four fever sessions of two and one-half hours each, at from 105 to 106 F. (rectal), given daily. She was discharged January 30, and since then there has been no recurrence of the chorea. The cardiac condition has improved and the digitalis has been discontinued.

CASE 9.—A girl, aged 11 years, entered as an outpatient Jan. 30, 1936, suffered from a first attack of moderate chorea. The onset occurred five weeks prior to admission and was associated with an emotional disturbance.<sup>8</sup> Treatment consisted of fifteen daily sessions of two and one-half hours each at from 105 to 106 F. (rectal). Improvement was noted after the first session and following the ninth treatment choreiform movements were noted only on attempts to perform finer coordinated movements. She was discharged February 20 as recovered. There has been no recurrence to date.

CASE 10.—A girl, aged 15 years, admitted Feb. 19, 1936, as an outpatient, suffered from her third attack of moderate chorea. The first attack occurred at the age of 4 and was of several weeks' duration. The second attack of chorea occurred at 11 years and was of one year's duration. The onset of the

7. This apparatus is described in detail in the following articles: (1) Simpson, W. M.: Artificial Fever Therapy in Syphilis, *J. A. M. A.* 105: 2132 (Dec. 28) 1935. (2) Desjardins, A. U.; Stahler, L. G., and Popp, W. C.: Fever Therapy for Gonorrheal Infections: II. *J. A. M. A.* 106: 960 (Feb. 29) 1936.

8. Ebaugh, F. G.: Neuropsychiatric Aspects of Chorea in Children, *J. A. M. A.* 87: 1083 (Oct. 2) 1926.

present attack occurred one month prior to admission. Treatment consisted of ten two and one-half hour fever sessions at intervals varying from one to seven days at rectal temperatures of 105-106 F. (Behavior difficulty of this child influenced the interval of treatment.) The patient was discharged March 12 as recovered.

CASE 11.—A married woman, aged 17, admitted to the hospital Feb. 25, 1936, had severe chorea in her first attack. The onset seven weeks prior to admission was associated with peritonsillar abscess and an emotional upset. Treatment consisted of ten daily sessions, two and one-half hours each, at from 105 to 106 F. (rectal). There was marked improvement after the second treatment and the patient was discharged March 10 as recovered. The severity of the attack required intravenous sodium amyltal sedation during the first treatment.

CASE 12.—A boy aged 8 years, was admitted to the hospital March 4, 1936, in his first attack of moderate chorea. The onset two months prior to admission was associated with rheumatic fever. Our examination revealed no positive cardiac changes. Treatment consisted of daily fever sessions of two and one-half hours each, at from 105 to 106 F. (rectal). He was discharged March 10, following six treatments, as recovered.

a period of forty days. We believe that this was an unusual case in that the attack began as a mild chorea and with fever became severe. Whether or not this severity was due to fever or would have been the natural course in this particular attack is a question. The average amount of fever administered in our cases was twenty-four hours at from 105 to 106 F. (rectal).

The fact that we have had no recurrences to date requires no comment, since the series of treatment was begun only a year ago.

It is our belief that the amount of shock following the injection of triple typhoid vaccine, as shown by chills, vomiting, severe headache, extremely high fever and marked prostration, is a serious contraindication when there is already a badly damaged heart. With artificial fever we are able to avoid such complications and, as our results show, we have had no complications. We believe that there is a distinct advantage of artificial fever produced by mechanical means over the foreign protein method. One advantage to the method that we

CASE 13.—A boy, aged 7 years, admitted to the hospital March 6, 1936, presented a chronic case of severe chorea. There had been no previous attacks. Treatment consisted of eight daily fever sessions, of two and one-half hours each, at from 105 to 106 F. (rectal). Marked improvement was noted after the first treatment and recovery was evident on March 14.

RESULTS

According to the accompanying table it should be noted that our cases have all been either moderate or severe. It is well known that the duration of chorea, whether treated or not, is usually prolonged, the average case lasting from six to ten weeks and some extending into months. When the interval between sessions was from three to six days (cases 1, 2, 3, 4, 5, 6, 7 and 10) it is noted that the duration of the treatment was naturally longer, averaging about thirty-four days. Since we have changed our policy of treatment to daily sessions (noted in cases 8, 9, 11, 12 and 13) the duration of treatment has dropped to an average of nine days.

At first we were conservative regarding the frequency of treatment because of the cardiac complications but found that our choreic patients could tolerate daily sessions without difficulty.

It should be noted that all our patients recovered. The longest duration of treatment (case 6) was over

have used is the controllability of the temperature. Treatment may be terminated instantly should unforeseen complications arise. Furthermore, a specified dose of fever may be administered at will. None of our cases showed loss of weight during the fever sessions. We are able to maintain an adequate fluid intake by mouth<sup>9</sup> with maintenance of the fluid balance. We feel that this is important, as all the severe and many of the moderate choreic patients are badly dehydrated.

SUMMARY

Thirteen cases of chorea have been treated by artificial fever with the Kettering hypertherm.<sup>10</sup> Results thus far have been excellent, with recovery in all cases. Advanced rheumatic endocarditis has not been contraindicative to treatment. To date there have been no recurrences of chorea, though the period of observation has been short. Mechanically induced fever has certain advantages over induction by triple typhoid vaccine.

4200 East Ninth Avenue.

9. From 2,500 to 4,000 cc of 0.6 per cent saline solution is used during each two and one-half hour fever session. The salt solution is necessary to replace chlorides lost by perspiration.

10. Since this paper was submitted for publication, we have treated seven additional cases of chorea; six of these patients have recovered, and one is still under treatment.

RENAL INSUFFICIENCY DEVELOPING  
DURING PROLONGED USE  
OF ALKALIS

REPORT OF A CASE

J. MURRAY STEELE, M.D.

NEW YORK

The occasional development of alkalosis during treatment with alkalis in individuals suffering from duodenal ulcer has, since Hardt and Rivers<sup>1</sup> description in 1913, been mentioned frequently in the literature<sup>2</sup> and may take place even when no alkali has been used, provided severe intestinal obstruction with loss of chloride ions and of acids occurs.<sup>3</sup> It has even longer been recognized that in renal disease alkalis may not be well tolerated,<sup>4</sup> and the appearance of alkalosis during a course of treatment involving their use has in fact been regarded as evidence that the kidneys were already injured. Hardt and Rivers<sup>1</sup> suggested that prolonged use of alkalis might injure the kidneys, even in the absence of preexisting renal disease. Cases of damage due to this source have subsequently been described by Houghton<sup>3</sup> and by Jordan.<sup>2</sup> Berger and Binger<sup>4</sup> have recently reported a case of renal disturbance in which the renal function was almost certainly normal both before and after the state of alkalosis was observed. In rats it has in fact been shown that feeding alkalis may be followed by severe hematuria although at autopsy no lesion of the kidney is found.<sup>5</sup>

In the case here reported the behavior of the kidneys was studied from the time when damage following the taking of alkali was detected until they once more functioned in a normal manner. In this case, as in Lloyd's, the usual neurologic manifestations of alkalosis, nausea, headache, nervousness and tetany, were absent.

## REPORT OF CASE

C. J., a man, aged 52, a lawyer, had had measles, chickenpox and malaria when he was a child. On several occasions he suffered from influenza. Attacks of tonsillitis were frequent until his tonsils were excised in 1914. Severe infections of his sinuses were frequent until 1930, when a medicinal preparation of some sort afforded him moderate relief. It appears that he complained of "minor stomach troubles" even as a young man. He first began to suffer from indefinite attacks of pain after eating in 1918. For this he took milk and antacid

powders. The diagnosis was thought to be "acid stomach" based on chemical examinations and on the examination of roentgenograms. His pain gradually ceased in about three months. In 1926 pain recurred, more definite than in 1918, appearing regularly from one to one and one-half hours after meals; this attack also was relieved readily when he resumed the milk diet. The third attack in the fall of 1928 was relieved in six weeks by a modified Sippy regimen, which included his taking seven doses of chalk and soda and several glasses of milk a day. In the spring of 1929 pain again occurred. On this occasion an appendicectomy was performed. Afterward he suffered from an attack of bronchopneumonia. When he recovered, the abdominal pain had subsided. The fifth and last attack occurred one year later, in the spring of 1930. He then began to take chalk and soda regularly four or five times a day. The patient believes that difficulties with his stomach have usually followed episodes involving nervous strain or prolonged periods of difficult work or more frequently anxiety concerning his son's welfare.

He remained fairly well until October 1932, when a new train of symptoms began. He became fatigued on the least effort, either physical or mental, and experienced nocturia five

\* A sample of urine for this measurement was obtained during the last twelve hours of a twenty-four hour period without fluids and on a dry type of diet.

† This high value has, in all probability, to do with incomplete emptying of the bladder before the beginning of the test, since the values for the separate hours were 190 per cent for the first and 106 per cent for the second hour.

or six times (for fifteen years he had been accustomed to urinate once during the night). He lost about 20 pounds (9 Kg.). November 30 he came for advice because, following the finding of albumin in the urine on two occasions and once a few hyaline and granular casts, his physicians had, in accordance with the knowledge of the course of Bright's disease, offered him a rather grave prognosis.

The patient was well built but lean. The temperature was 98.6 F. by mouth, the pulse rate 81 and respiration rate 20 per minute. The height was 173.5 cm. and the weight 63.2 Kg. The skin was sallow. The ears, nose and throat were essentially normal. There was considerable dental work. The mouth was clean. Engorgement of the peripheral veins was absent. The lungs were clear. The heart was not enlarged to percussion or in the roentgenogram. The aorta was slightly widened. The sounds of the heart were clear and the second sound at the base was somewhat accentuated. A systolic murmur was heard at the apex. The rhythm of the heart was regular. In his electrocardiogram the electrical axis deviated to the left and the T<sub>2</sub> wave was negative. The pulse at the wrist was of fair force. The walls of the radial arteries were just palpable. The arterial pressure measured 164 mm. of mercury systolic, 90 diastolic. Examination of the abdomen brought to notice nothing abnormal. The liver, spleen and kidneys were not felt. There were no masses or areas of tenderness. Edema

of the legs was not present. On fluoroscopic examination and in roentgenograms of the upper gastro-intestinal tract a persistent deformity of the duodenal bulb was found on filling with a barium sulfate meal, which suggested to the examiner the presence of duodenal ulcer. At no time was an outline of the opaque medium seen which suggested actual filling of the crater of an ulcer. On ophthalmoscopic examination slight sclerosis and some tortuosity of the retinal arteries and indentation of the veins were apparent. Observations with regard to the urinary constituents and renal function are more easily comprehended in the form of a table. December 1 the ability of the kidneys to excrete urea and to concentrate the urine was markedly impaired. The level of the urea nitrogen in the blood was elevated. The presence in the sediment of casts was taken as evidence that renal damage was, at the moment, taking place. The reaction of the urine to litmus was alkaline.

This patient, then, while taking large doses of alkali daily for the relief of abdominal pain, was found to be suffering from diminution of renal function of sufficient magnitude to elevate the urea nitrogen level of the blood. A moderate degree of general arteriosclerosis was present. It was thought that taking alkalis might have played a part in increasing the damage to kidneys already the seat of changes of arteriosclerotic Bright's disease. He was instructed, therefore, to refrain from taking alkalis except for the relief of pain, and a diet designed to contain little residue was recommended. Viosterol and liver extract were added to complete the diet. He was discharged December 2.

In the latter part of February 1933 he suffered severe intestinal hemorrhage while in Egypt. In addition to a more restricted diet, bismuth carbonate, triple basic magnesium phosphate and olive oil were prescribed. On May 4, except for a gain in weight of 5.31 Kg., there was little change in his general physical state. He said, however, that he felt less fatigued than he had for some time. Tests of renal function and examination of the urine were repeated. Considerable improvement had occurred as is brought out in the accompanying table. He was then taking a bland diet, six "alucol" (colloidal aluminum hydroxide) tablets and a pint of milk daily. Other alkalis were not used. Since this time there have been no gastro-intestinal complaints. Steady gain in weight, relief from ready fatigue and decrease in frequency of nocturia followed and, as can be seen from the table, apparent recovery from the renal disturbance. Within six months the blood urea nitrogen returned to normal and has remained so since. In ten months the urea clearance rose to a normal level and has remained so. The power of the kidneys to concentrate the urine rose slowly to normal during a period of two years. Casts (almost entirely hyaline) and red blood cells continue to be present in numbers no greater than those normally encountered, and faint traces of albumin appear from time to time in the urine.

#### COMMENT

The course of this patient's illness illustrates several points which deserve emphasis. It appears that an individual may consume relatively large quantities of alkali for a number of years before signs of renal dysfunction appear. Second, it is worthy of comment that evidence of severe renal injury may occur before the development of obvious symptoms of alkalosis. This sequence of events has been noted by Lloyd.<sup>3</sup> In this instance fatigue and nocturia were the only complaints. Third, judging from the improvement of renal function subsequent to cessation of the use of alkalis, it appears unlikely that renal lesions, which if present must have been extremely slight, could have been responsible for the retention of alkalis. Fourth, the observation of Binger, Hastings and Neill<sup>7</sup> and of Myers and Booker<sup>8</sup>

that some individuals with apparently normal kidneys cannot readily excrete alkali is important. The subject of the present report does not, however, appear to belong to their group, since the urine was alkaline to litmus. Unfortunately, there is no evidence to show that alkalosis existed, since the notion that disturbance of the acid-base balance of the blood may have taken place was not recognized until after considerable improvement had occurred. Finally, in this condition as well as in the usual varieties of nephritis, as Alving and Van Slyke<sup>9</sup> have pointed out, recovery of the power of the kidneys to concentrate urine lags well behind the recovery of the ability to secrete urea.

#### SUMMARY

The use of alkali through a span of many years for the relief of pain due to a duodenal ulcer was followed eventually by the passage of albumin, red blood cells and casts in the urine, and the appearance of severe renal insufficiency, as indicated by elevation of the urea nitrogen of the blood and marked decrease in the ability of the kidneys to excrete urea and to concentrate the urine. Recovery followed discontinuance of the use of alkalis. This train of events occurred in the absence of signs of alkalosis.

Sixty-Sixth Street and York Avenue.

## CAROTENEMIA IN DIABETES

WALTER HEYMANN, M.D.

CLEVELAND

Xanthosis in diabetes is due to an accumulation of lipochrome pigments in the blood, the most conspicuous of which has proved to be carotene. Some authors<sup>1</sup> explain the hypercarotenemia occurring in diabetes by the increased content of carotene in the diabetic diet; others,<sup>2</sup> however, believe that the accumulation of carotene in the blood of diabetic patients is due to a disturbance in the metabolism of carotene which is connected with the metabolic disturbance due to the diabetes. This question deserves more than merely theoretical interest, because the biologic importance of carotene as the precursor of vitamin A is generally accepted.

I have tried to solve the problem by studying the response of the carotene content of the blood in diabetic and in nondiabetic subjects after the administration by mouth of a solution of carotene in oil (0.3 Gm. of carotene per hundred cubic centimeters of oil).

Table 1 shows that the carotene in oil given to healthy subjects in a single dose by mouth appears in the blood rather late, that is, certainly not during the first four hours but from eight to twelve to twenty-four to thirty-six hours after its administration, in spite of the fact that the solvent oil may be grossly recognized by the milky appearance of the serum from one to two hours

after administration. The most likely explanation of the delayed appearance of the carotene in the blood serum is that the pigment may be temporarily retained in the liver.

In order to determine the carotenemic reaction after enteral administration of the pigment to diabetic and nondiabetic subjects, it was consequently necessary to administer the carotene for four consecutive days, in three daily doses of 2 cc. each, and to determine the carotene content of the blood every second day for the two weeks following. Connor's<sup>3</sup> method was used, with the slight modifications described in a previous paper.<sup>4</sup>

Table 2 gives the essential clinical data concerning the ten diabetic children on whom the studies were made, and in the upper half of the accompanying chart are presented curves showing the effect on the carotene content of their blood serum. The figures in the first column of table 2 correspond to those placed at the beginning of each curve in this part of the chart, each curve thus representing the child so numbered in table 2.

The curves in the lower half of the chart show the effect on the carotene content of the blood serum of the twelve nondiabetic subjects who were used as controls. These were healthy children, free from infection of any kind, and were of the same age as the diabetic children.

The marked differences between the curves for the diabetic and the nondiabetic children may be easily seen. In the first place, as has already been stated, the fasting level of carotene is higher in the blood of the diabetic subjects, the average value being 0.592 mg. per hundred cubic centimeters compared with 0.254 mg. in the control group.

It can be seen from the data in table 2 that the degree of hypercarotenemia runs parallel to the duration of the diabetes except in the case of child 6, who had a definite hypercarotenemia in spite of having suffered from the disease for only two months. The parallelism between the fasting level of the carotene in the blood serum and the duration of the diabetes does not, however, answer the question whether the hypercarotenemia in diabetes is caused by a dietary or by a metabolic factor.

In order to eliminate the possible nonspecific influence of ketosis, which was present to greater or less extent in each of the diabetic patients studied, five of the nondiabetic children were placed on a ketogenic diet in which the ketogenic-antiketogenic ratio varied from 2.5:1 to 4:1. The results obtained with these five children are recorded by the broken lines and open circles in the lower half of the chart.

The second deviation, noticeable when the curves for the diabetic children are compared with those for the healthy children, occurs in five of the ten diabetic children. I have in mind the more or less marked retardation in increase in the carotene content of the blood serum after the administration of the carotene solution to children 1, 3, 4, 6 and 9. The data presented in table 2, however, show that these five children were ill with infections, while the remaining five diabetic patients, who did not show a retarded increase in carotene content of the blood serum, were free from infections.

Investigations by Clausen<sup>5</sup> and myself<sup>4</sup> have definitely shown that infections, whatever their nature may be, interfere greatly with the intestinal absorption of this pigment. The kind of interference just referred to in diabetic patients has been described by Clausen and by myself in nondiabetic children suffering from infections. Since this retarded absorption was not observed in the diabetic children who were free from infections (children 2, 5, 7, 8 and 10), there is consequently no doubt that the deviation from the normal as revealed by the curves has nothing whatever to do with the diabetic condition.

The third and specific deviation shown by the curves of the diabetic patients lies in the decreasing limb of the curve. If infections have not interfered with a sufficiently distinct increase in the carotene content of the

Curves showing the effect on the carotene content of the blood serum after administration of carotene in oil by mouth to ten diabetic and twelve nondiabetic children for four consecutive days, in three daily doses of 2 cc. each. The curves in the upper half of the chart show the carotenemic response in the diabetic children and are numbered to correspond with the clinical data for these children given in table 2. The curves in the lower half of the chart show the carotenemic reaction in the nondiabetic, healthy children used as controls. The broken lines and open circles represent the response in the five children in whom a ketosis was established by a ketogenic diet.

blood serum (as is the case in all the diabetic children studied except children 6 and 9), the curves remain elevated, failing to show the normal decline after the administration of carotene has been discontinued, or they even keep on rising (children 1, 2, 3, 4 and 10) for a period of from ten to fourteen days. The normal shape of the curves obtained in the five healthy children in whom a definite ketosis and acetonuria were induced by ketogenic diet rules out the possibility that the pathologic shape of the diabetic curves might have been due to the accumulation of ketone bodies. The nature of the diabetic hypercarotenemic reaction corresponds to the hyperglycemic

response obtained in diabetic patients after the oral administration of sugar when the normal decline of the increased sugar content is similarly retarded. The analogous carotenemic reaction in diabetes, accordingly, can be regarded as a symptom of faulty utilization of carotene.

It is not surprising to find that the high fasting level of carotene in the blood serum, as well as the hypercarotenemic reaction, persists in diabetic patients who have been clinically sufficiently provided with insulin. The efficacy of insulin is known to increase slowly, to reach its peak after from two to three hours, and subsequently to decrease during the next two to three hours. Even when two or three doses of insulin a day are given, there still remain from six to twelve or more

between the diabetic carotenemia and the hypercholesterolemia, becomes unlikely because it has furthermore been shown<sup>2b</sup> that the diabetic hypercholesterolemia and hypercarotenemia do not always parallel each other. I therefore would prefer to look on the disturbance of the carotene metabolism occurring in diabetes as another and thus far not well understood consequence of the faulty utilization of sugar, just as the pathologic utilization of fat and cholesterol in diabetes is regarded.

## SUMMARY

The blood serum carotene curves obtained in ten diabetic children after the administration by mouth of carotene in oil were distinctly different from those obtained in twelve nondiabetic, healthy children and

† The carotenemic reaction of these children is shown in the accompanying chart, the curves in the chart being numbered to correspond to the numbers in this table.

hours in which the intermediary carbohydrate metabolism cannot be regarded as entirely normal. The large fluctuations seen in the blood sugar level (table 2) in diabetic children to whom insulin was being given in adequate doses demonstrate clearly what has already been stated. It is clear, therefore, that the fasting level of the blood sugar and the fasting level of the carotene content of the blood of diabetic patients do not parallel each other, as has been pointed out by Rabinowitch.<sup>2b</sup> This fact, consequently, does not speak against the assumption that the faulty utilization of carotene demonstrated in these studies in diabetic patients is primarily related to the disturbance of the carbohydrate metabolism.

Another possible explanation of the hypercarotenemic reaction described in this paper, namely, the relationship

demonstrated that the metabolism of carotene is interfered with in diabetes.

The carotene content of the blood, when it was once increased in the diabetic patients, failed to show the normal decline and remained elevated or even kept on increasing for from ten to fourteen days after the administration of the carotene in oil had been discontinued. The analogy with the hyperglycemic reaction after sugar is given by mouth to diabetic patients is striking and speaks in favor of assuming that the utilization of carotene has been interfered with in diabetes.

The diabetic carotenemia can consequently no longer be explained merely by the high carotene content of the diabetic diet.

## ORCHITIS AND OOPHORITIS PAROTIDEA (OSLER)

## REPORT OF TWO CASES

A. P. OHLMACHER, M.D.

ROYAL OAK, MICH.

Orchitis as a complication of mumps is a commonplace incident, the frequency of which has been placed by some authors<sup>1</sup> at between 10 and 25 per cent of cases, while others quote an incidence as high as 50 per cent<sup>2</sup> in certain epidemics. It is said that the orchitis may appear in from two to sixteen days after the parotitis, and most commonly in from four to eight days. The fever tends to persist for from two to six days and falls by lysis. A rather imposing proportion of atrophy, as high as 60 per cent according to Catrin,<sup>3</sup> is said to occur in the absence of operation, which, briefly, has in the reported cases consisted in the making of incisions in the tunica albuginea. Vezeaux de Lavergne and Florentin,<sup>4</sup> and Teissier recommend convalescent serum as an effective prophylactic against orchitis.

Ovarian involvement is uncommon enough to warrant more than passing attention, and but few and isolated instances of this phenomenon are recorded in the literature. Involvement of either the male or the female gonad is definitely inclined to appear as a late complication. According to Osler,<sup>5</sup> "the orchitis may occur before the parotitis, or in rare instances may be the only manifestation of the infection (orchitis parotidea)." He states succinctly that "involvement of the ovaries is rare."

The fact remains that cases of primary orchitis due to the virus of mumps are out of the ordinary,<sup>6</sup> while orchitis parotidea sans parotitis is observed but seldom. Bieberach and Vider in a recent report have added a case of the latter type to the literature, which previously contained, according to them, only sixty-four instances of this condition. Dillard<sup>7</sup> discusses certain facts of diagnostic importance and quotes, almost verbatim, the scholarly description of the pathology written by S. B. Wolbach, which was included in an article by George G. Smith.<sup>8</sup> The ovaries, perhaps owing to their relatively secure and protected position, are, as already stated, rarely involved even as a secondary complication. Mastitis and pancreatitis (abdominal mumps), uncommon sequelae of parotitis, are yet less unusual than oophoritis. Harlow Brooks<sup>2</sup> reports two cases of secondary oophoritis and concludes that the phenomenon is very unusual. He further emphasizes the benign nature of the ovarian involvement quite in distinction to the frequent destructive effects on the male cell. There is, to my knowledge, no reported case of primary oophoritis due to mumps without subsequent parotitis.

while primary ovarian inflammation followed at an interval by parotid disease has been cited but exists only as a curiosity. Gueit<sup>9</sup> in 1913 reported a somewhat doubtful case of primary oophoritis in a woman, aged 21, in which the parotitis ensued on the sixth day following the onset of the abdominal symptoms. This author, as well as Brooks, mentions the differential confusion arising between right-sided oophoritis of this type and appendicitis, particularly in view of the fact that the pathologic changes in question are prone to present themselves in young individuals in whom careful pelvic examinations may not be feasible.

The following reports present an instance of the unusual orchitis parotidea sans parotitis along with one of the very exceptional primary oophoritis due to the virus of mumps:

## REPORT OF CASES

**CASE 1.—History.**—A man, aged 27, single, the occupant of a rooming house, first seen on Oct. 18, 1929, complained chiefly of pain in the region of the right testicle, which in a few hours exhibited definite and progressive swelling, accompanied by pronounced tenderness to pressure. Concomitant aching sensations in the muscles of the lower part of the back and legs ensued, with symptoms of fever and prostration. The patient stated that there had been no urethral discharge and no recent venereal exposure. Interrogation revealed the existence, about two and one-half weeks previously, of cases of typical mumps in two of the landlord's children, and the fact that a third child was showing ominous symptoms.

The patient was positive that he had never had mumps. He likewise stated that he had not had a venereal disease.

**Examination.**—The patient was well nourished and muscular, and examination presented no important physical changes with the following exceptions: The temperature was 100 F. and the pulse 94. The right portion of the scrotum was moderately swollen and rather tense and showed increased local temperature. Careful palpation gave the impression that the swelling involved both testicle and epididymis, both of which had increased to about twice the normal dimensions. The process impressed one as being definitely less fulminant than the average case of gonorrheal origin; that is, there was less local heat, not such extreme tenseness, and a less exquisite tenderness to pressure.

Laboratory examination, October 18, revealed 7,800 white blood cells, with 38 per cent polymorphonuclears, 57 per cent lymphocytes, 4 per cent large mononuclears and 1 per cent eosinophils. November 2 the white blood cells numbered 7,600, with 60 per cent polymorphonuclears, 36 per cent lymphocytes and 4 per cent large mononuclears. The urine, October 18, was normal.

**Treatment and Progress.**—The patient was confined to bed, a nest of absorbent cotton fitted around the involved organ, and adhesive tape applied for suspension. The process began to subside after four days and the patient became ambulant on the tenth day. Increased firmness of the testicle to palpation persisted, but at eight months no atrophy was discernible. At no time during the course of this condition was any involvement of the salivary or other remote glandular structures observed.

**CASE 2.—History.**—A robust girl, aged 18 years, admitted May 2, 1932, complained chiefly of pain in the right lower quadrant of the abdomen.

The patient stated that she had been annoyed by a "slight stomach ache" for about forty-eight hours. Six hours before she presented herself this mild symptom was superseded by a severe cramplike pain localized in the right lower quadrant. Some nausea was present but no vomiting. There had been no evidence of recent respiratory infection. Her last menstrual period had terminated about ten days previously, and there had been no subsequent vaginal discharge. She had not defecated during the twenty-four hours prior to admission and had indulged in no catharsis or enemas prior to admission. Urinary symptoms were absent.

8. Smith, G. G.: Two Cases of Orchitis, Due to Mumps, Treated by Operation, *Boston M. & S. J.*, 1912.

The past history was irrelevant except for the fact that intermittent attacks of transient abdominal pain had been observed for the past two years. She felt that these attacks were similar to the onset of the present illness.

**Examination**—The patient was in considerable pain. The temperature was 99 F., pulse 100. The blood pressure was 118 systolic, 80 diastolic. There was no suggestion of a pathologic condition above the diaphragm. Abdominal palpation revealed tenderness rather definitely localized to the right lower quadrant, where spasm of the rectus muscle was elicited. There was no costovertebral tenderness. No evidence of discharge or inflammatory reaction was present about the introitus or the urethra. Digital rectal examination, combined with abdominal palpation, elicited pain, the source of which was thought not to be in the uterine adnexa.

Catheterized urine was entirely negative. A blood count was not done at this time. A blood count taken May 6 revealed 9,000 total white blood cells, with 30 per cent polymorphonuclears, 65 per cent lymphocytes, 4 per cent large mononuclears and 1 per cent transitionals.

**Treatment and Progress**.—In view of these observations we were unable to rule out appendicitis, and, accordingly, a laparotomy was performed. The appendix was found to be somewhat injected but otherwise grossly normal and was not considered to be the instigating factor. It was, however, removed as a routine. Palpation of the pelvic structures revealed a considerable enlargement of the right ovary. This was visualized and estimated to be about one and one-half times larger than its fellow on the left. It was firm and elastic to palpation and had a peculiar edematous appearance. The surface presented an unusual bluish tint, interspersed with a few very minute petechiae. Since no impression of an ordinary inflammatory or purulent change was manifested, the abdomen was closed without drainage.

For forty-eight hours the postoperative progress was uneventful. On the third day, however, the temperature, which had not exceeded 100 F., abruptly rose to 102, and the patient complained of aching sensations in both parotid areas. Swelling appeared and rapidly became extreme, presenting the picture of an unusually high degree of bilateral mumps. A rather disquieting reaction was provoked by this sequence of events, and marked prostration with striking elevation of pulse and considerable local distress persisted for about sixty hours, at which time an abrupt amelioration of the symptomatology ensued. There was at no time any suggestion of suppuration, fluctuation or other sign that we were dealing with a condition any different from the epidemic type of parotitis; the parotid swelling abated gradually, while the surgical convalescence, apparently not distorted, was uneventful.

#### COMMENT

It is interesting to recall the rather definite similarities existing in the appearance of the involved ovary in case 2 and that of the testicles exposed at operation by other workers.<sup>10</sup>

There would seem to be little doubt concerning the authenticity of this case of oophoritis parotidea. No other logical explanation for the appearance of the ovary, especially in the light of subsequent developments, can be readily advanced. It is unfortunate that a specimen for microscopic study was not obtained. The whole subsequent clinical picture, including the general physical condition of the patient, the chronological sequence of events leading to the development and subsidence of the parotid involvement and the physical characteristics of the salivary protuberances was definitely not that of the suppurative postoperative type of parotitis. We were convinced, incidentally, that the exposure and manipulation of the offending ovary were important factors in the prompt development and full blown picture assumed by the parotitis. Whether without operation the parotids would have

remained unsullied and the case run its course ("full many a flower is born to blush unseen") as one of oophoritis parotidea sans parotitis is idle speculation.

It is probable that this excessively unusual pathologic process will always present enough similarity to acute appendicitis to suggest operative intervention strongly, even granting that watchful waiting and astute differential diagnostic efforts would surely be rewarded by cognizance of the true state of affairs.

## GONORRHEAL VAGINITIS

### RESULTS OF TREATMENT WITH DIFFERENT PREPARATIONS AND AMOUNTS OF ESTROGENIC SUBSTANCE

ROBERT M. LEWIS, M.D.

NEW HAVEN, CONN.

AND

ELEANOR L. ADLER, M.D.

NEW YORK

In 1933 one of us<sup>1</sup> described the administration of estrogenic substance as a practical method of treating gonorrheal vaginitis in children. Eight cases treated in this way with marked success were reported. The fact was established that sufficient estrogenic substance given to girls would bring about a temporary maturation of the undeveloped vaginal mucosa. The clinical results in these cases indicated that therapy with estrogenic substance was likely to be successful. Edgar Allen<sup>2</sup> had previously described a similar reaction induced in immature monkeys by treatment with estrogenic substance.

Since the publication of this article a number of reports on the results of therapy with estrogenic substance have appeared in the literature.<sup>3</sup> With one exception (so far as we know) each author has reported gratifying results.<sup>4</sup> Witherspoon<sup>5</sup> reported a total of ten cases treated without benefit. He used, however, a relatively small daily or nearly daily dosage of a preparation which both we and TeLinde have found unsatisfactory. In other reports therapy with estrogenic substance has yielded satisfactory and, in some cases, brilliant results.

During the past two years a study, generously financed by the Milbank Foundation, has been conducted in the Children's Medical Service of Bellevue Hospital, Department of Pediatrics, New York University. Supplementary work has been carried on in

From the Department of Obstetrics and Gynecology, Yale University School of Medicine, and the Children's Medical Service, Bellevue Hospital, New York University Department of Pediatrics.

4 Since completing this paper our attention has been called to a report by R. B. Phillips (*New England J. Med.* **213**: 1026-1029 [Nov. 21] 1935). Phillips treated thirteen cases of true gonococcal vaginitis or suspicious cases with theelin in oil—from 2,310 to 2,970 international units per week. All cases eventually yielded negative smears, but "pus" relapsed. Of these nine, three yielded positive smears and six "pus" relapsed.

5 Witherspoon, J. T. *Treatment of Gonorrheal Vulvovaginitis in Childhood with the Ovarian Follicular Hormone*, *Am. J. Dis. Child.* **50**, 913 (Oct.) 1935.

the New Haven Hospital by Alfred Cohn, Louis Weinstein and others. In all, 165 children with gonorrheal vaginitis have been diagnosed and treated by different methods. Various preparations and amounts of estrogenic substance have been used. In this paper only those giving definite results are mentioned. A number of cases in which results were inconclusive because of irregular or inadequate treatment are not included.

In our experience treating gonorrheal vaginitis of children with various local antiseptics has often proved difficult, and the results have usually been unsatisfactory. The number of preparations available are legion and no one can have tried all that are recommended. Generally speaking it is difficult to see how antiseptics can be relied on to destroy organisms that have penetrated and are thriving beneath the epithelium. We thought originally that the mere histologic change involved in temporarily converting the very thin vaginal mucosa of the child to the far thicker and partly cornified structure of the adult adequately explained the destruction of the invading gonococci. Further studies have convinced us that the curative result is in all likelihood due not to the histologic change alone but to a striking change in the reaction of the vaginal secretions. The nearly neutral reaction normal in childhood changes to a marked acidity which always accompanies the temporary maturation of the mucosa.

In view of the results with estrogenic substance that we as well as others have obtained, we believe that our

first impression was correct; namely, that in gonorrheal vaginitis of children the infection is ordinarily confined to the vaginal mucosa and submucosa and that the endocervix is but rarely involved. It goes without saying that the cervix should be inspected for infection in every case in which this can be done without too much difficulty. In all cases in which infection lingers after adequate therapy, the cervix should be examined even if anesthesia is required to get a clear view. If endocervical infection is found in the unusual case, cauterization is indicated.

It is recognized that positive smears and positive cultures of gonococci can often be obtained from the rectum in cases presenting gonorrheal vaginitis.<sup>6</sup> This was confirmed by Alfred Cohn in those of our patients whom he studied. In eleven cases that yielded gonococci on vaginal smears, four cultures from the rectum also gave positive results. The rectal infection appears to be superficial and clears up in the great majority of

cases *pari passu* with the vaginal infection. Only rarely does a deep-seated proctitis become troublesome.

There is a great divergence of opinion as to the average duration of gonococcal vaginitis treated with antiseptics. TeLinde found that four months was an average at the Johns Hopkins Clinic for cases so treated. We have found an average of four and a half months' duration in a series of thirty-five cases treated in the New Haven Hospital. A longer follow up might well have increased the length of our average figures. The Bellevue-Yorkville study<sup>7</sup> reports 241 cases under observation for from about five to sixteen months. Of 124 cases studied, forty-seven, or 37.9 per cent, were infected for from one to eleven years before admission to the clinic. The authors of this study conclude that three or four months of treatment with mercurochrome will render the vaginal smears of 70 per cent of such cases negative or "suspicious." We have seen cases of two and three years' duration and heard of one instance in which the infection lasted seven years.

In our cases the criterion for a diagnosis of gonorrheal vaginitis has been the finding in the vaginal smear of gram-negative diplococci morphologically resembling gonococci. In the limited number of our cases in which cultures or complement fixation tests were conducted, an extraordinarily high percentage of the diagnoses made by smears were confirmed. Dr. Alfred Cohn of the Department of Bacteriology at Yale University School of Medicine found that in twelve smears of positive cases ten gave positive cultures. In twenty-five smear-positive cases, complement fixation tests by Cohn and the Department of Health Laboratories, New York City, gave eighteen positive results, three doubtful and four negative.

Cases are reported in this paper as negative when no gonococci or pus cells were found on repeated smears. All such cases should be seen and smears should be examined for many months after an apparent cure has been effected.

7. Brunet, W. M.; Tolle, D. M.; Scudder, S. A., and Medcalf, A. R.: Report of a project of the Bellevue-Yorkville Health Demonstration of New York City, reprinted from Hospital Social Service Magazine, sup. 1, March 1933.

During the first part of our study the patients were under the direct care of Dr. Helen Owen.

Sixty-six patients treated with 800 international units daily of estrogenic substance<sup>8</sup> in ethylene glycol given hypodermically yielded some results but on the whole rather unsatisfactory ones.

TABLE 3.—Summary of Results\*

Case	Age	Duration Before Treatment	Total Dosage, International Units	Days Treatment Until Negative	Follow-Up	
					Time	Result
1	3½ yrs.	3 days	21,600	14	5 mos.	Apparently well
2	3 yrs.	1 wk.	37,200	28	.....	Recurred in 1½ mos.
3	6 yrs.	2 wks.	21,600	14	5 mos.	Apparently well
4	4 yrs.	1 wk.	23,480	10	5 mos.	Apparently well

33	9 yrs.	5 wks.	45,800	12 wks.	7 wks.	Apparently well

\* Children with gonorrheal vaginitis treated by means of estrogenic suppositories, one inserted into the vagina each night. Some suppositories contained 600 international units of estrogenic substance. Those used more recently contained 1,000 international units.

A further follow up of the cases treated with estrogenic substance in suppository form, observed through the four-month interval since this paper was written, showed that all but five patients have remained well for periods ranging from four to nine months. Patient 26, who was considered as being probably still infected, proved to have a persistent urethritis which was in all likelihood responsible for a relapse after two months. Cases 16, 17, 22 and 28 recurred after from two and a half to four months. These have all cleared up promptly under a second course of estrogenic substance, as did the three recurrent cases reported in the text.

Eight more cases in which treatment has been completed since this report was compiled, became negative in an average of 19.7 days. Only one case in the forty-eight cases treated with the suppository form of administration has failed to show the response to administration of estrogenic substance.

With this dosage (800 international units daily) twenty-seven cases became negative after treatment varying from two to twenty-two weeks, apparently with response to estrogenic substance. Six cases remained

positive in spite of continuous treatment for from eighteen to thirty weeks, with no evidence of estrogenic reaction. Two of these patients were found to have an endocervicitis. Eight cases that recurred shortly after treatment was stopped were not considered to have been satisfactorily treated.

The remaining cases gave insufficient evidence from which to draw conclusions. Some became negative after very small doses of estrogenic substance and before any tissue reaction was observed; some in which treatment was interrupted while smears were still positive returned at a later date presenting negative smears. A few did not remain under observation after treatment was stopped. Many of the patients receiving only 800 international units of estrogenic substance by hypodermic daily showed only doubtful vaginal reactions. We have determined the presence or absence of response of vaginal mucosa to the different preparations and dosages used in this study by examining microscopic sections of minute biopsies.

Increasing the dosage of estrogenic substance in ethylene glycol yielded better results. Eight ward patients with gonorrheal vaginitis were given daily by hypodermic 2,400 international units in divided doses (table 2). Negative smears were obtained from this group in an average time of 24.2 days. They were followed thereafter for from two weeks to nine months. Three of these cases recurred, one in one month and two in two months. These cases were again treated until negative smears were obtained and have remained negative for from one to three months. No cases were treated with estrogenic substance in oil parenterally.

In the original paper<sup>1</sup> mention was made of the use of vaginal suppositories containing theelin. These were discarded at that time as not effective. It is probable that the amount of estrogenic substance contained in them was not sufficient to produce the desired vaginal reaction in a large percentage of the cases in which they were used.

Recently TeLinde and Brawner reported the use of vaginal suppositories containing 600 international units of estrogenic substance in cases of gonorrheal vaginitis. Their results were surprisingly and uniformly satisfactory. Twenty-two patients were treated and in all of them the infection disappeared, as evidenced by clinical observation and negative smears, in an average of from 17.8 to 29.4 days. They found that on an average 13.1 days was required to produce the initial characteristic response of the vaginal mucosa to estrogenic substance.

Of seventeen cases, five recurred but quickly yielded to a second course of treatment with estrogenic suppositories. Although little time had elapsed in some of their cases after apparent cure, all smears were negative when last examined.

Since hearing TeLinde's paper in June 1935, we have treated a series of thirty-three patients at Bellevue Hospital with estrogenic suppositories. At first suppositories of estrogenic substance containing 600 international units each were used. Recently this preparation was changed by the manufacturer to one containing 2,000 international units. One half of such a suppository containing 1,000 international units was inserted into the child's vagina each night before she went to bed. No vaginal washes or applications were used. The external genitalia were washed when necessary for cleanliness. The patients have been followed and observed for evidences of the estrogenic reaction and the development

8. The large amount of estrogenic substance (amniotin) required in all our work has been given to us most generously by E. R. Squibb & Sons.

of negative smears. Vaginal biopsies examined microscopically have shown that the estrogenic reaction of the vaginal mucosa has occurred regularly.

It is of course of the utmost importance to determine the presence or absence of the vaginal response to estrogenic substance in all cases, as without this tissue change no benefit can be expected. This was formerly done by securing minute biopsies and examining sections with the aid of the microscope. This method is time consuming and expensive. Vaginal smears showing extraordinary desquamation of epithelial cells are evidence that the estrogenic reaction has occurred. The inexperienced observer will, however, often be misled, particularly if the exfoliation is not great. The gross appearance of the vaginal mucosa and introitus is frequently helpful.

We wish now to stress the value of another simple practical test for the estral response which can be carried out easily in a few minutes. Long ago Döderlein<sup>9</sup> called attention to the presence of the bacillus named for him and considered its acid-forming properties as responsible for the acid reaction of the secretions of the adult female vagina. Zweifel later showed that it was the destruction of the superficial glycogen containing cells of the vaginal mucosa that produces much of the acidity. In the thin vaginal mucosa of the child but little glycogen is contained. On the other hand, the superficial cells of the adult vagina and, of more importance to us, of the vagina of the child adequately treated with estrogenic substance are loaded with glycogen. These as a result of bacterial or enzymatic action produce a markedly acid reaction as they break down. Soeken,<sup>10</sup> Cruickshank<sup>11</sup> and others have described the histologic changes that occur during puberty and ordinarily before the occurrence of the first menstrual period. They have also pointed out the dramatic and abrupt change to acidity in the reaction of the vaginal secretion which occurs at this time and that this in turn is accompanied by an equally rapid transformation of the vaginal flora.

Hall and Lewis<sup>12</sup> treated immature monkeys hypodermically with estrogenic substance and found that the vaginal secretions, which are faintly alkaline ( $p_H$  7.5 to 8) in the normal animal, became suddenly strongly acid ( $p_H$  5.4 to 5.7) as soon as the vaginal response to estrogenic substance occurred. In normal children the reaction of the vaginal secretions is nearly neutral (usually between  $p_H$  6.8 and 8.4). We confirm Lewis and Weinstein's<sup>13</sup> observations which show that when the vaginal mucosa of children reacts to estrogenic substance the vaginal secretions change from near neutral to a well marked acidity ( $p_H$  4.8 to 6).

In vitro the gonococcus grows best in a faintly alkaline medium ( $p_H$  7.2 to 7.6). If this is rendered acid very gradually over a period of days or weeks these organisms will rarely adapt themselves to a medium as acid as  $p_H$  6 to 6.2. Usually the culture dies before this point is reached. Tests that we have carried out to determine the  $p_H$  of the vaginal secretions of children in our series before treatment have given  $p_H$  values between 6.8 and 7.4. With the appearance of the estrogenic reaction of the vaginal mucosa (checked by

biopsy and microscopic section), the vaginal secretions became acid ( $p_H$  4.5 to 6.2), nearly always giving readings below 6.

In the few cases in which this reaction did not occur, either as a result of neglect in the administration of the estrogenic substance or because of some unknown constitutional factor which prevented the usual vaginal response to estrogenic substance, the infection ordinarily continued. Nearly every case in which the  $p_H$  of the vaginal secretions dropped to below 6 recovered from the gonococcal infection. Consequently we believe this acid change of the vaginal secretion is the important curative factor produced by administration of estrogenic substance in gonococcal vaginitis of children.

It is a simple matter to determine the  $p_H$  reaction of the vaginal secretions. The vagina is irrigated with 1 or 2 cc. of neutral physiologic solution of sodium chloride adjusted to a  $p_H$  of 7.0. Colorimetric readings of the  $p_H$  of the washings are made with brom-thymol-blue, brom-cresol-purple or brom-cresol-green as indicators, depending on the degree of acidity present. The

Duration of treatment with estrogenic substance required to yield negative smears.

results are read by comparisons with a set of standards. If an acidity below 6.2 is found it may be taken as evidence that the desired change in the vaginal mucosa has been brought about. This is much simpler and less time consuming than the taking of biopsies. When  $p_H$  readings in our cases were below 6.0, biopsies invariably showed that the vaginal mucosa had reacted to estrogenic substance. If readings remained near or above 7.0, no change had occurred, as the treatment had been inadequate.

The use of suppositories of estrogenic substance, as suggested by TeLinde and Bawner, has enormous advantages in point of simplicity over any other form of treatment with which we are acquainted. The treatment is readily carried out at home by any intelligent adult and needs only a weekly visit to the physician or dispensary. It is not uncomfortable for the little patient, as contrasted with the usual local applications or with our own earlier method of treatment by the hypodermic route. It is also apparently much more efficacious and less apt to cause temporary enlargement of the breasts. The use of the suppositories every night should continue for at least two weeks after the discharge ceases and smears have become negative. None of our cases have shown any stimulation of mammary

development and none have exhibited bleeding from the uterus. None of our cases have shown any evidence of harmful results from the treatment. The treatment with suppositories must be carried out regularly. Irregular or inadequate treatment is no better than no treatment at all.

It is generally recognized that long-standing cases of gonorrheal vaginitis yield to estrogenic therapy more easily than do the recently acquired florid cases. In our group of thirty-three consecutive cases treated with suppositories of estrogenic substance practically all (table 3) were of the latter class.

Of a total of thirty-three cases treated with estrogenic suppositories in the manner that we have just described, in thirty the smears were negative in an average of 20.7 days. Patients 32 and 33 continued to have slight discharge and gonococci, until eventually after twelve weeks they appeared well. Case 31 showed negative smears for three successive days but is in all likelihood still infected.

Of the thirty-three patients five have had recurrences. Three of these had a return of purulent discharge and gonococci. Two have had no further vaginal discharge but a return with gram-negative diplococci in their smears. These two cases are being kept under observation. Of the other three recurrent cases, two now show negative smears after seventeen and twenty-eight days of further treatment with suppositories. The other recurrent case was started on a second course of treatment seven days ago and will probably clear up rapidly.

Two of the patients who appeared to have recurrences had presumably acquired their initial infections from an actively infected member of the household. Apparently cured of vaginitis in the ward, they were of necessity returned to their homes, where in each case the parent continued to be a likely source of fresh infection. We have classified these cases as recurrences although they may well have been reinfections.

#### CONCLUSIONS

1. In treating gonorrheal vaginitis, estrogenic substance in ethylene glycol given hypodermically was relatively effective when used in large doses: 2,400 international units daily. Eight hundred international units daily proved disappointing.

2. The use of vaginal estrogenic suppositories (originally 600 international units and later 1,000) proved very effective.

3. Clinical improvement, cessation or great diminution of discharge is nearly always noted after from fourteen to eighteen days of treatment.

4. The administration of estrogenic substance changes the reaction of the vaginal secretions from neutral or alkaline to acid. This, we believe, is the major factor in eliminating the gonococcic infection.

5. The acidity of the vaginal secretions is easily measured and provides a sure guide by which one can determine whether or not dosage is adequate.

6. Of thirty-three consecutive cases of gonorrheal vaginitis in children treated with estrogenic suppositories, thirty yielded negative smears in an average of 20.7 days. Two required twelve weeks of treatment. Five cases are listed as recurrences.

7. No ill effects were encountered. We believe that this method of treatment is safe and harmless.

8. We consider the use of vaginal estrogenic suppositories the most effective method known for the treatment of gonorrheal vaginitis in children.

## THE FEEDING OF MODIFIED GASTRIC JUICE IN PERNICIOUS ANEMIA

FREDERIC M. HANES, M.D.

O. C. HANSEN-PRÜSS, M.D.

AND

J. W. EDWARDS

DURHAM, N. C.

In a recent issue of *THE JOURNAL* Greenspon<sup>1</sup> offered an explanation of the rôle played by the gastric secretions in hematopoiesis that differs essentially from Castle's well known theory of the interaction of intrinsic and extrinsic factors. By feeding a pernicious anemia patient normal gastric juice so treated as to inhibit the action of pepsin, Greenspon states that a degree of reticulocytosis was produced which is comparable to the effect of liver therapy in pernicious anemia. It is obvious that such an experiment might easily be vitiated by the presence of "extrinsic factor" either in the stomach of the patient or in the gastric juice of the donor.

We have repeated Greenspon's experiment, adhering strictly to his technic, in five typical untreated cases of pernicious anemia. Fifteen normally healthy medical students have acted as donors of gastric juice, which in every instance has been tested for the presence of free hydrochloric acid. One donor with achlorhydria was rejected. Histamine (0.1 mg. per kilogram of body weight) alone was used to stimulate the flow of juice, and if there was evidence of food contamination the specimen was discarded.

CASE 1.—A man, aged 39, a farmer, gave a typical history of pernicious anemia of two years' duration. He had not been treated. The usual objective signs of pernicious anemia without involvement of the spinal cord were observed.

Examination of the blood on admission revealed hemoglobin 4.4 Gm. (28 per cent), erythrocytes 1,140,000, color index 1.25, mean corpuscular volume 122 cubic microns, leukocytes 2,150, reticulocytes 0.5 per cent and plasma bilirubin 0.5 mg. per hundred cubic centimeters.

Gastric analysis revealed no free hydrochloric acid after histamine (0.1 mg. per kilogram of body weight) subcutaneously.

After an observation period of four days during which the reticulocytes did not rise above 1 per cent, neutralized (tenth normal sodium hydroxide) and chilled gastric juice was fed by tube for nine days in doses of 340, 250, 250, 200, 260, 230, 200, 290 and 350 cc., a total of 2,370 cc. During the nine days of the gastric juice feedings and for four days thereafter there was no rise in the reticulocytes or erythrocytes, and the patient felt worse in every way. The appetite decreased.

Three intramuscular injections of 10 cc. of solution liver extract concentrated-Lilly (each cubic centimeter derived from 33 Gm. of liver) were given on successive days, and on the fourth day of liver treatment the reticulocytes rose to 20 per cent and increased steadily to 40 per cent on the sixth day after the first injection. The erythrocytes increased to 1,500,000. The mean corpuscular volume fell from 122 cubic microns on admission to 89.1 cubic microns nine days after the administration of gastric juice was begun. On the sixth day of liver treatment the mean corpuscular volume had increased to 123 cubic microns.

CASE 2.—A man, aged 58, a farmer, presented the classic history and objective signs of pernicious anemia of eight months' duration. He had not been treated.

Examination of the blood on admission revealed hemoglobin 5.4 Gm. (36 per cent), erythrocytes 1,170,000, color index 1.13, mean corpuscular volume 110, leukocytes 4,150, reticulocytes 0.4 per cent and plasma bilirubin 1 mg. per hundred cubic centimeters.

From the Department of Medicine, Duke University School of Medicine.

1. Greenspon, E. A.: The Nature of the Antipernicious Anemia Principle in Stomach: I. Method to Improve Stomach Preparations. *J. A. M. A.* 106: 266 (Jan. 25) 1936.

Gastric analysis revealed no free hydrochloric acid after histamine (0.1 mg. per kilogram of body weight) subcutaneously.

After five days of observation during which the reticulocytes did not rise above 0.2 per cent, seven daily feedings of neutralized chilled gastric juice by tube were given in doses of 260, 280, 250, 175, 260, 260 and 270 cc., a total of 1,750 cc. Eight days after the first feeding of gastric juice the reticulocytes rose to 1.8 per cent and during the next six days counts of 2, 3, 3, 2.6, 3 and 1 per cent were made.

Liver therapy was begun seven days after the last gastric juice feedings. Ten cubic centimeters of solution liver extract concentrated-Lilly was given intramuscularly on two successive days. On the fourth day of liver therapy the reticulocytes had risen from 1 to 7.8 per cent and during the next five days rose to 39 per cent. The erythrocytes during the same time rose to 2,250,000. During the course of gastric juice feedings the mean corpuscular volume fell from 110 cubic microns to 71 cubic microns. On the sixth day of liver feeding the mean corpuscular volume had risen to 103 cubic microns.

CASE 3.—A man, aged 46, a farmer, had pernicious anemia of six years' duration; there was subacute combined degeneration of the spinal cord. He had received no liver therapy.

Examination of the blood on admission revealed hemoglobin 6.6 Gm., erythrocytes 1,570,000, color index 1.3, mean corpuscular volume 123, leukocytes 2,200, reticulocytes 0.2 per cent and plasma bilirubin 1 per cent.

Gastric analysis revealed no free hydrochloric acid after the injection of histamine (0.1 mg. per kilogram of body weight) subcutaneously.

After six days' observation, during which the reticulocytes never rose above 0.6 per cent, seven feedings of neutralized chilled gastric juice were given by tube in doses of 250, 250, 250, 180, 305, 250 and 300 cc., a total of 1,785 cc. During the period of the gastric juice feedings and for three days thereafter the reticulocytes did not rise above 1 per cent.

Acting on a suggestion which Dr. Castle had made in a letter to Dr. Greenspon, the patient was placed on the following dietary restrictions three days prior to the feeding of gastric juice and during the seven days of gastric juice feedings. The purpose of the diet was to exclude "extrinsic factors" as far as possible. "No meat, eggs, chicken, vegetables or fruit. Milk allowed in cooking and in tea or coffee. Diet to consist of white bread, rice, butter, macaroni, small amounts of ice cream, tea and coffee"; (quoted from a letter from Dr. Greenspon). On this diet, combined with gastric juice feedings, the patient grew steadily worse.

On the fourth day after the last feeding of gastric juice, liver therapy was given as follows: first day, 10 cc. of solution liver extract concentrated-Lilly; second day, 20 cc. of Parke, Davis & Co.'s liver extract for intravenous use (derived from 100 Gm. of liver); third and fourth days, 10 cc. of solution liver extract concentrated-Lilly. On the fourth day of liver therapy the reticulocytes were 10 per cent and rose to 42 per cent, as a maximum, on the fifth day.

During the course of gastric juice feedings the mean corpuscular volume fell from 123 cubic microns to 92 cubic microns and then rose to 119 cubic microns on the sixth day of liver therapy.

Two other patients with untreated pernicious anemia were given neutralized gastric juice, in exactly the manner detailed, with totally negative results. For the sake of brevity their detailed histories are omitted.

Sternal bone marrow studies in all five cases were done at frequent intervals during the periods of gastric juice feedings, and in no instance was the usual megaloblastic picture changed. The megaloblast-normoblast ratio remained unaltered throughout the experiments and was identical with that constantly seen in untreated pernicious anemia.

#### CONCLUSION

Feeding pernicious anemia patients the gastric juice of normal individuals, modified according to the technic of Greenspon, produces no subjective or objective improvement in the patient's condition. No evidence of increased erythropoiesis was observed, either in bone marrow or in circulating blood.

## Clinical Notes, Suggestions and New Instruments

### MULTIPLE SYMMETRICAL LIPOMATOSIS

J. K. MILLER, M.D., INGLESIDE, NEB.  
Neuropathologist, Hastings State Hospital

Lipomas may occur anywhere within the body and have been found in the cranial cavity, the mediastinum, the uterus and the marrow cavity of the bones. Because of their wide distribution they have been classified as subcutaneous, intermuscular and visceral. The majority are located under the skin and occur most frequently on the trunk, thighs and arms. The face, scalp, sternal region, hands and lower legs are infrequent sites.

Pack and LeFevre,<sup>1</sup> in a study of 19,129 tumor cases, of which 2,564 were benign growths, found that lipomas included

Fig. 1.—Multiple symmetrical lipomatosis: Distribution of the lipomas on the son, showing freedom of the hands and lower part of the legs and the presence of four tumors above the neck.

4.3 per cent of all benign tumors. Adair,<sup>2</sup> reporting the regional distribution of 352 lipomas in 134 patients, had a frequency of from 4 to 5 per cent of all benign tumors. Of these, nine cases (6.7 per cent) were multiple lipomas. Adair included a case presenting 160 distinct tumors. Of the 352 lipomas, only two

Fig. 2.—Multiple symmetrical lipomatosis: Distribution of the lipomas on the daughter, showing freedom of the hands, lower part of the legs and the head.

tumors were observed above the neck, two below the knees and two on the hands. Of the 134 patients, 101 were between the ages of 30 and 55; 42 per cent were in the decennium of 40-50 years. Females constituted approximately 75 per cent of the cases.

Adair differentiates between multiple lipomas and "congenital diffuse lipomatosis." The latter is confined to one or two limbs

From the Clinic of Dr. E. C. Foote, M.D., Hastings, Neb.  
1. Pack, G. T., and LeFevre, R. G.: The Age and Sex Distribution and Incidence of Neoplastic Disease at the Memorial Hospital, *J. Cancer Research* 14: 167-294 (June) 1930.  
2. Adair, F. E.; Pack, G. T., and Farrior, J. H.: Lipomas, *Am. J. Cancer* 16: 1104-1120 (Sept.) 1930.

and is usually associated with corresponding enlargement of muscles and bones of the same extremity. The multiple lipomas, Adair believes, are neurolipomas. They are not congenital but develop during adolescence and later life. Their frequent symmetrical distribution commonly confuses them with multiple neurofibromatosis. Adair presents a number of clinical similarities but, in suggesting a neurogenic origin for multiple lipomas, admits a lack of histologic evidence.

The etiology of symmetrical lipomatosis is obscure. Ewing<sup>3</sup> says: "It has not been possible to establish for lipomas such a relation to peripheral nerves as exists with fibromas." Adair has called attention to a number of writers who have linked the lipomas with neuropathies. Trauma and endocrine imbalance, particularly of the thyroid and pituitary, may be provocative agencies. Again, Ewing says that lipomas (multiple) "seem more closely connected with the forms of diffuse or regional overgrowths of fat tissues, which bear the same relation to lipomas as diffuse fibromatosis to fibromas." He believes that endocrine imbalance of the thyroid and pituitary may be an important factor. "A congenital tissue predisposition seems to be an essential factor in the origin of most lipomas." Moreira da Fonseca<sup>4</sup> qualifies multiple symmetrical lipomatosis as an "endocrinosympathetic syndrome," with emphasis on the pituitary.

A heredofamilial tendency in multiple lipomas is illustrated by the reported cases of Adair, Bonnefous and Valdiguié,<sup>5</sup> Cannon,<sup>6</sup> Esquier<sup>7</sup> and Leven.<sup>8</sup> Adair has one report of the condition extending through three generations.

#### REPORT OF CASES

The following three cases of multiple symmetrical lipomatosis were observed in a mother, a son and a daughter:

CASE 1.—The mother was a white woman, aged 63. At the age of 35 her menses suddenly ceased and in the following five years she began to note the appearance of small, soft tumors over her body. A few were noted on the lower part of the legs and many on the scalp. Most of the tumors were from 0.5 to 1 cm. in diameter and were frequently associated with pigmented nevi. The tumors were not painful or attached to the skin. The total number of tumors was too great for the patient to diagram accurately. Her son and daughter presented similar tumors the location of which is shown in the illustrations.

CASE 2.—The son, aged 34, at the age of 14 years was struck on the left cheek with a baseball, and three years later he noted a soft tumor over the area and a second soft tumor under the left upper eyelid. Coincidentally a tumor appeared in the roof of the mouth. The oral tumor grew slowly but when the patient was 34 it had acquired the size of a hen's egg (3 cm. in diameter). The necessity for removal brought these three cases to the attention of the physician.

CASE 3.—The daughter, aged 36, first noted the tumors at the age of 26. Four years before admission she had one of the large abdominal tumors (5 cm. in diameter) removed. Biopsy revealed a lipoma. At the present time she gave no history of endocrine imbalance.

#### COMMENT

The son and daughter each presented seventeen lipomas and the distribution in the two cases was similar (figs. 1 and 2). No tumors were noted on the lower legs or on the hands. However, the son presented four tumors of the head and the mother presented numerous soft tumors of the scalp. The mother also showed a number of lipomas of the lower legs. A suggested endocrine imbalance is noted in the cessation of menses in the mother prior to the appearance of the tumors.

Histologic examination of the oral tumor from the son revealed a preponderance of fat cells of a mature type. However, the cytology was characterized by interlacing bundles of

mature fibrous tissue. Although there was no histologic evidence of neurogenic origin, the distribution of the tumors in the son and daughter suggests a possible configuration following the peripheral nerve routes. A second tumor removed from the son showed a simple mature lipoma.

#### SUMMARY

Three cases of multiple symmetrical lipomatosis in a mother, son and daughter were observed. The tumors were noted in uncommon sites, namely, the head and lower part of the legs, on the mother and son. The distribution of the tumors on the son and daughter (seventeen in each case) was similar. Possible endocrine disturbance may have been an etiologic factor in the mother.

## Special Article

### DIPHTHERIA MORTALITY IN LARGE CITIES OF THE UNITED STATES IN 1935

#### THIRTEENTH ANNUAL REPORT

This report concerns the ninety-three cities dealt with in the recent article on typhoid;<sup>1</sup> the rates are calculated on the basis of the population figures used in that article. The number of diphtheria deaths in each city has been reported to us by the respective health departments.<sup>2</sup> Particulars as to the years that are included in the five year averages, annotated as "incomplete data" are given in footnotes to tables 1-8 in our previous reports through 1931 and are itemized at the beginning of the article for 1932.

# Incomplete data

twenty-eight deaths from diphtheria in 1935 in the whole New England group (population 2,624,805) is remarkable (table 13). New Haven has easily borne off the palm since 1930 among the New England cities. It is tempting to attribute this freedom from the disease in New Haven to the high proportion of immunized children (65 per cent of children of preschool age and 80 per cent of school children). The city of Lowell, although still with more diphtheria than the average, shows marked improvement over 1934. Boston again has a very low rate for a city of its size.

The eighteen cities of the Middle Atlantic states (table 2) still rank as the best geographic group in the country as regards diphtheria mortality (table 13). Only three cities had a rate higher than 20 and eight of the eighteen had no diphtheria deaths, Syracuse for the third consecutive year. The Middle Atlantic cities are running a close race with the New England cities, the diphtheria rate for the group for 1935 (1.00) being only slightly lower than the New England group aver-

age (1.07): this was also the case in 1934 (Middle Atlantic 1.63, New England 1.68). Utica is said to have had only one case of diphtheria in 1935. 61 per cent of children under 5 years of age in that city have been given the immunizing treatment. Here also it is impossible to avoid the conclusion that the very large extent to which diphtheria immunization is practiced in the cities in this region is responsible for the marvelously low, and still declining, diphtheria death roll. New York records the lowest rate in its history (0.9) and Philadelphia, with a rate of 1.0, is on the same level. It is noteworthy that, of the nineteen cities in the United States reporting no diphtheria deaths in 1935 (table 10), fifteen are in the two geographic divisions just discussed (New England and Middle Atlantic).

The nine cities of the South Atlantic group (table 3) did not, on the whole, do as well in 1935 as in 1934, Wilmington, Washington, Miami and Tampa showing an increase in diphtheria mortality. Jacksonville alone in this group shows marked improvement. Baltimore has an exceptional record in this division. For a period

of a year and sixteen days (Sept. 26, 1934, to Oct. 13, 1935) there was not a single resident diphtheria death. Here also the campaign for diphtheria prevention by immunization has been carried on actively, apparently with a high degree of success. What is the matter with the other cities along the South Atlantic seaboard? One would expect Washington to have as low a rate as

Baltimore, but the average diphtheria mortality for the last two years has been nearly ten times as great. Cities like Miami or Tampa, with a "good climate," ought certainly to bring their diphtheria rates down to a level with those of the cities in "bleak" New England and central New York.

The cities in the East North Central states (table 4) had a relatively poor diphtheria year, the divisional

# Incomplete data.

group rate rising from 1.89 in 1934 to 2.45 in 1935, an increase which suggests that renewed efforts in some communities should be made to bring about a general inoculation of children. Cincinnati is said to have had a high proportion of nonresident deaths (six to be credited to Kentucky and one each to Indiana and Ohio). The Peoria death rate from diphtheria was very high in the first six months of the year and it is stated that the improvement observed in the second six months was due to the general application of immunizing methods. It should not, however, be necessary

to wait until a considerable number of children are attacked before general immunization is undertaken. The results of preventive inoculation are now so definite that there seems no longer any excuse for continued high diphtheria mortality in either Northern or Southern cities.

The East South Central cities (table 5) in 1935 show a marked group improvement (table 13) over 1934 in diphtheria mortality. This is particularly marked in Louisville, Chattanooga and Nashville. Knoxville and Memphis have not done so well. Knoxville, as will be seen in table 5, shows an increase in the quinquennial period 1930-1934 as compared with 1925-1929, and, if 1934 and 1935 are representative, there seems likely to be another increase for the current five year period. It appears in table 9 that Knoxville had the highest diphtheria rate in the United States for 1935. Even allowing for considerable diphtheria in the surrounding

country, the rate is still far too high for any American city in view of our present knowledge of methods of combating this infection.

The death roll in the West North Central division (table 6) in 1935 shows some improvement over 1934; this is particularly marked in the case of St. Louis and Kansas City, Kansas. The St. Louis rate appears to be the lowest ever recorded by that municipality. This is true also for Minneapolis and St. Paul, with the relatively low rates of 0.6 and 0.7, respectively. Duluth seems to have been remarkably free from diphtheria for a number of years and is likely to hold its place in the present decade as the leader in the West North Central group; the disease is said to have practically disappeared from that city.

The West South Central states (table 13) remain in almost exactly the same position as in 1934, a slight increase from 5.48 to 5.58 being indicated. While Oklahoma City, El Paso, Houston and New Orleans (table 7) show a noteworthy diminution in diphtheria mortality, the decrease in El Paso being particularly

gratifying, Fort Worth and San Antonio are backsliders. The residents of these Southwestern cities may well ask themselves why they should lose five times as many of their children from diphtheria as residents in the New England and Middle Atlantic states.

The cities in the Mountain and Pacific states (table 8) experienced higher diphtheria mortality in 1935 than in 1934, the increase in Oakland being particularly striking. San Francisco had a good record, although not quite so amazing as in 1934.

TABLE 12—Total Diphtheria Death Rates for Eighty-Eight Cities, 1923-1935\*

	Population	Diphtheria Deaths	Diphtheria Death Rate per 100,000 Population
1923	31,060,848	4,678†	13.13
1924	31,722,841	3,499	10.84
1925	32,384,834	3,133	9.67
1926	33,046,827	3,106	9.40
1927	33,708,820	3,493	10.36
1928	34,370,813	3,176	9.24
1929	35,032,806	2,738	7.82
1930	35,694,802	1,827	5.12
1931	36,356,812	1,346	3.74
1932	37,018,812	1,191	3.21
1933	37,684,812	861	2.32
1934	38,346,812	821	2.23†
1935	39,008,812	764	2.08†

\* The five following cities are omitted from this summary because data for the full period are not available: Jacksonville, Miami, Oklahoma City, South Bend and Utica.

† Data for Fort Worth lacking.

‡ The rate for the ninety-three cities in 1935 is 2.09 (population 37,437,812, diphtheria deaths 782). The corresponding rate for 1934 was 2.26 and the average for 1930-1934 was 3.34.

As appears in table 11, the number of cities with diphtheria death rates over 10 decreased from four in 1934 to two in 1935 and those with no diphtheria deaths increased from fifteen to nineteen. For the eighty-eight cities in our tables (table 12), the number of diphtheria deaths reported in 1935 was 764 as compared with 821 in 1934 and 3,133 in 1925, ten years ago. The rate for the whole population was probably definitely

TABLE 13—Total Diphtheria Death Rates per Hundred Thousand of Population for Ninety-Three Cities According to Geographic Divisions

	(1933) Population	Diphtheria Deaths		Diphtheria Death Rates	
		1935	1934	1935	1934
New England	2,624,895	28	44	1.07	1.68
Middle Atlantic	12,952,900	129	211	1.00	1.63

lower in 1935 than in 1934, but, since population estimates at the present time are tentative, the actual figures given in table 12 are of course only approximations.

The striking feature in the 1935 diphtheria record appears to be that wherever preventive inoculation against diphtheria is practiced consistently diphtheria deaths well-nigh cease to occur, and in some communities diphtheria morbidity is also reduced to an insignificant figure. It is to be hoped that all communities will soon come to realize what can be done in the matter of diphtheria prevention.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE. HOWARD A. CARTER, Secretary.

### HEATING OF HUMAN TISSUES BY SHORT WAVE DIATHERMY

JOHN S. COULTER, M.D.

AND

HOWARD A. CARTER, B.S. IN M.E.

CHICAGO

In heating human tissues by short wave diathermy, claims have been made that certain wavelengths are more effective than others. A survey of current literature reveals many opinions. Apparently none of the authors have investigated the heating effects of different frequencies of short wave diathermy energy on living tissues of the human thigh. There are many references to heating of dead tissues and agar agar solutions.

Schereschewsky,<sup>1</sup> in his studies of dead tissues, found that a 4.69 meter wavelength had a greater heating effect on muscle than a 1 meter wavelength.

Schliephake<sup>2</sup> performed his experiments by placing pieces of individual tissues of equal size in the condenser field, at the same time taking care to keep the field strength as constant as possible. Amputated arms and legs likewise were used. He investigated wavelengths ranging from 3.5 meters to 14 meters, employing seventeen different wavelengths in all. He concluded that the heating of individual tissues in a unit of time varied when energy of certain wavelengths was used. When treating dead pieces of tissue he observed that the fat was usually strongly heated, although the absolute height of the temperature varied. Animal fat gave different values from human fat. Furthermore, fatty tissues of different men gave different values. Schliephake's explanation for this was that fat is a storehouse for various kinds of minerals. Schliephake stated that, in a leg examined by him, the maximum heating of fat was obtained with 14.5 meters and the minimum with 7 meters. He further stated that there was quite commonly a decrease in the heating effect on all kinds of tissues when wavelengths of 17 meters were exceeded.

Gebbert,<sup>3</sup> as quoted by Kowarschuk,<sup>4</sup> found the heating of fat and muscle the same with wavelengths from 3 meters to 16 meters in his study of the influence of different wavelengths from a condenser field on the heating of muscle, bone, fat and bone marrow (dead tissue).

Bachem<sup>5</sup> used 3.5, 5, 7 and 15 meter wavelengths in his studies on dead tissues. With these wavelengths there was little difference in the heating effect in the muscle of the dead tissues. He found that the strongest heating of the subcutaneous fat was observed with the 5 meter wavelength, which gave a comparative temperature increase of 4 degrees C., while the 15 meter gave about 2.2 degrees C.

Schliephake<sup>2</sup> gave heating curves for muscles close to the bones, the medial muscles, and the boundary

<sup>5</sup> Bachem, A. Selective Heat Production by Ultrashort Waves, Arch. Phys. Therapy 16: 645-650 (Nov.) 1935.

between subcutaneous fat and muscles. The maximum heating for these tissues was observed at 14 or 15 meter wavelengths, and the minimum at 7 meters.

Holzer and Weissenberg,<sup>6</sup> in their work on dead tissues, showed that there was approximately 200 watts more heating with a 20 meter wavelength than with 10 meters when calculating the heat production in watts per ampere for cubic centimeters of tissue.

In the heating of dead human tissues it is possible to obtain different heating effects with energy at different wavelengths, but there is a considerable difference in the opinion of the investigators about the heating of fat and muscle. Schliephake noted that the maximum heating of fat was at 14.5 meters and the minimum at 7 meters. Gebbert observed no difference between 3 meters and 16 meters. Bachem found the greatest heating at 5 meters.

In the heating of muscle, Schereschewsky noted that there was a greater heating with a 4.69 meter wave than with 1 meter. Gebbert observed no difference between 3 meters and 16 meters. Schliephake noted that the maximum heating of muscle was at 14.5 meters. Holzer and Weissenberg found a greater heating of muscle at 20 meters than at 10 meters.

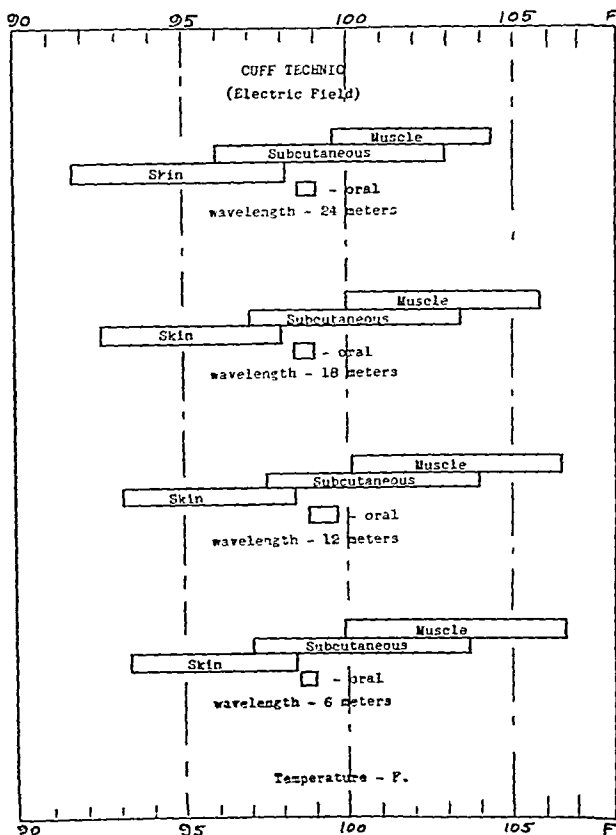

Chart 1.—Relation between wavelength and temperature with cuff electrode method.

In reviewing the aforementioned results, we can agree with Schliephake in his statement "From the results obtained on parts of dead bodies, we cannot conclude as to the results on living human beings," and with Kowarschik,<sup>4</sup> who states that unfortunately we do not know the electrical constants for most tissues and that what is known is very questionable.

Our investigation was undertaken because, apparently, there were no records in literature of heating living human tissues by short wave diathermy machines of different wavelengths. Therefore, this study was made to determine the heating efficacy of short wave diathermy in living human fat and muscle of the thigh, employing, first, an electric field of 6, 12, 18 and 24 meter wavelengths, using the cuff electrode technic;

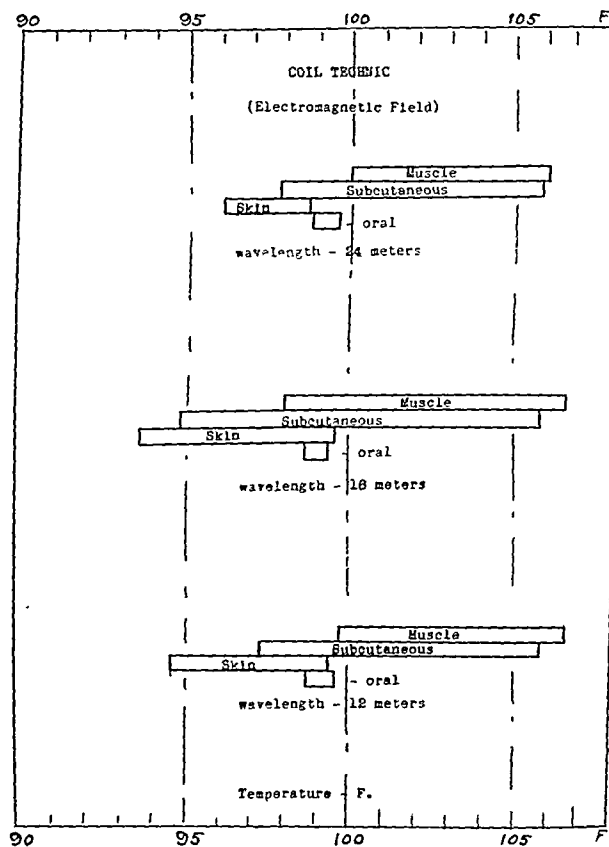

Chart 2.—Relation between wavelength and temperature with coil technic.

secondly, an electromagnetic field of 12, 18 and 24 meter wavelengths, using the coil technic. The cuff electrode of the electric field and the coil of the electromagnetic field were selected because previous work by Mortimer and Osborne<sup>7</sup> showed these methods of application to be the most effective of those in general use for heating tissues.

The machine used in these tests was so designed that the oscillator circuit could be interchanged, thus giving the range of wavelengths aforementioned. Furthermore, arrangements were made for application by either electromagnetic or electric field technics. Temperatures were taken by three thermocouples made of copper and constantan wires (28 gage Leeds-Northrup double cotton covered), soldered into the tip of a 16 gage lumbar puncture needle. The thermocouples were connected to the potentiometer (Leeds-Northrup portable precision type) through parallel double pole switches, a method that facilitated rapid reading of the individual couple.

The thermocouples were calibrated against a Bureau of Standards calibrated thermometer with scale division in one-tenth degree Fahrenheit. Since the thermocouple

7. Mortimer, Bernard, and Osborne, S. L.: Tissue Heating by Short Wave Diathermy. Some Biologic Observations, J. A. M. A. 104: 1415 (April 20) 1935

itself was affected by the high frequency currents, there were no thermocouples in place in the field during the passage of the current.

The six human subjects were medical students who volunteered for these tests. Under aseptic precautions, a nonmagnetic nonconducting sheath (through which the thermocouple needle could be guided for temperature readings) was inserted subcutaneously and into the quadriceps extensor muscle. Temperatures of the skin, of the subcutaneous tissue, of the muscle and of the mouth were taken before and after a twenty-minute clinical application. The temperature of the patient was permitted to return to normal after each test.

The intensity of the current was governed by the patient's tolerance; that is to say, the subject agreed to stand as much of the current as was possible without suffering discomfort.

The size of the cuff was approximately 18 inches by 3 inches. One cuff was wrapped around the proximal part of the thigh and the other around the distal part of the thigh. The distance between the edges of the cuffs was about 6 to 8 inches. Under the cuffs, padding consisting of three thicknesses of felt and toweling was

the electromagnetic method, was lower than comparable initial temperatures of other wavelengths. Scrubbing with soap, applying disinfectants and injecting the anesthetic preparatory to inserting the cannula made the thigh cooler for the first observation than for the six subsequent observations. In the initial average temperature of the 18 meter wavelength, two of these first or low temperature readings were included instead of one reading as in the other averages. This explains the low initial average temperature of the 18 meter subcutaneous temperature readings of the electromagnetic field. Each final temperature reading was within the experimental error of the average of the six observations; hence these readings are regarded as more significant.

A practical and social problem becoming more and more important is the interference of short wave diathermy energy with radio communications. Mimno<sup>8</sup> reported that radio interference originating in a standard commercial short wave diathermy machine near the Harvard campus was picked up at the Naval Laboratory, Bellevue, D. C. The automatic keyed signals on 11.8 kilocycles (25.4 meters wavelength) were broad-

#### Summation of Results

18	100.05	105.73	5.68	97.03	103.35	6.32	92.52	97.98	5.46	98.35	99.08	0.73
12	100.13	106.45	6.32	97.48	105.98	8.50	91.13	98.42	7.29	98.80	99.66	0.86
6	99.93	106.58	6.65	97.12	103.68	6.56	91.33	98.40	7.07	98.50	99.07	0.57
Coil Technic, Electromagnetic Field												
24	99.97	106.05	6.08	97.72	105.81	8.11	96.08	98.71	2.63	98.77	99.00	0.23
18	97.98	106.72	8.74	94.82	105.77	10.95	91.62	99.58	7.96	98.70	99.35	0.65
12	99.73	106.60	6.87	97.33	105.83	8.50	94.75	99.37	4.62	98.07	99.00	0.93

used. Under the four turns of coil there was one-half inch of felt padding.

A summation of the results is given in the accompanying table. It shows the initial and final temperatures and also the temperature rises. The results are the average of six observations at each wavelength.

Chart 1 shows the relation between wavelength and temperature with the cuff electrode method.

Chart 2 shows the relation between wavelength and temperature with the coil technic.

The power input of these machines ranged from approximately 400 to 800 watts. There did not appear to be any satisfactory method of measuring the output in terms of electrical units. Several methods have been suggested to measure output, but not one of them faithfully records the amount of power used by the patient undergoing treatment.

A discussion of the probable sources of error in observations seems advisable. With our potentiometer-thermocouple hookup the temperature could be read to an accuracy of 0.2 degree Fahrenheit. Although the surgeon was able to place the cannula fairly accurately in the quadriceps extensor muscle, the placing of the cannula for observing subcutaneous temperatures was not so easily accomplished. The depth below the skin of the inner end of the cannula varied as much as 3 or 4 mm. in the six subjects. This unavoidable inaccuracy may be one reason for the slight differences of reading from subject to subject, especially in the subcutaneous temperature readings.

The average initial subcutaneous temperature observed with the 18 meter wavelength, using the coil technic of

cast by a short wave diathermy machine which was not equipped with an antenna, the high frequency radiation being fed back unintentionally through the power supply line. An interesting observation made by him was that the signals were hardly audible several miles from the source but were of good signal strength at the Naval Laboratory. This apparently affords proof of the fact that the radio wave was strongly reflected by the ionized regions of the upper atmosphere.

Two remedies have been proposed: one<sup>9</sup> is the allocation of a special wavelength band for therapeutic purposes and the other is the proper screening of short wave diathermy machines and equipment. If, in subsequent investigations, a single frequency was found to be satisfactory for all treatments, the oscillators would have to be stabilized so that deviation of no more than a kilocycle from this assigned frequency would ever occur. Short wave diathermy machines would have to be manufactured with a frequency stability corresponding to a good radio transmitter. This remedy would necessarily increase the original cost and the maintenance expense. If the second remedy should be adopted, radio-frequency filters or wave traps would have to be inserted in the power leads to prevent reradiation of the high frequency energy back into the power mains, and the treatment room would have to be screened and grounded. The additional expense of this installation would increase the original cost of the

9. Short Wave Diathermy—"The Shadow," editorial, J. A. M. A. 106: 1094 (March 28) 1936.

machine. Because of the ever increasing need for radio communication channels, it would seem that the method of screening and line filtering takes precedence over the allocation of a wave band for therapeutic purposes.

#### CONCLUSION

In the heating of live human muscle and fat there were no significant differences in the use of 6, 12, 18 and 24 meter wavelengths when using the cuff technic of the electric field method and no significant differences in the use of 12, 18 and 24 meter wavelengths when using the coil technic of the electromagnetic field method.

### Committee on Foods

THE COMMITTEE ON FOODS HAS HAD BEFORE IT THE PERPLEXING PROBLEM OF THE VITAMIN D FORTIFICATION OF MILK. A STUDY WAS UNDERTAKEN BY DR. PHILIP C. JEANS, AT THE SUGGESTION OF THE COMMITTEE, FOR THE PURPOSE OF OBTAINING CERTAIN FACTUAL DATA THAT MIGHT AID THE COMMITTEE IN THE FORMULATION OF FUTURE POLICIES. DR. JEANS HAS PRESENTED TO THE COMMITTEE ON FOODS A REVIEW OF THE LITERATURE ON THE SUBJECT. BECAUSE OF THE VALUABLE MATERIAL IN THE REVIEW, THE COMMITTEE ON FOODS HAS AUTHORIZED PUBLICATION OF THE REPORT WITH THE VIEW OF AIDING PHYSICIANS, THE PUBLIC AND THE MILK INDUSTRY TO A BETTER UNDERSTANDING OF THE PROBLEM. IN SO DOING, THE COMMITTEE TAKES OPPORTUNITY TO EXPRESS ITS GRATEFUL APPRECIATION TO DR. JEANS FOR THE TIME HE HAS DEVOTED TO THE SUBJECT AND FOR THE PREPARATION OF THIS REPORT.

FRANKLIN C. BING, Secretary.

#### VITAMIN D MILK

##### THE RELATIVE VALUE OF DIFFERENT VARIETIES OF VITAMIN D MILK FOR INFANTS: A CRITICAL INTERPRETATIVE REVIEW

PHILIP C. JEANS, M.D.

IOWA CITY

In this presentation an attempt is made to evaluate in relation to the human infant the relative potencies of the different varieties of vitamin D<sup>1</sup> as found commercially in vitamin D milks. Orientation in this endeavor is aided by a brief consideration of the relative values as determined for the experimental animal.

#### EXPERIMENTAL WORK WITH ANIMALS

The animals used chiefly are the rat and the chick. The lesser potency of irradiated ergosterol as compared to cod liver oil has been established beyond any reasonable doubt when these two materials are fed on an equal rat unit basis in experiments with the chicken. The numerical difference found depends chiefly on dietary and other variants in the experiments with chickens and has varied somewhat with different observers. The report of Bethke, Record and Kennard,<sup>2</sup> which includes a brief review of preceding studies, seems to establish the ratio of efficacy of cod liver oil to irradiated ergosterol at 1:15 to 20.

On the basis of rat unitage it has been found that cod liver oil, irradiated milk and irradiated cholesterol are of equal value to the chicken.<sup>3</sup> Calciferol<sup>4</sup> (a crystalline vitamin D) irradiated yeast<sup>4</sup> and milk from cows fed irradiated yeast<sup>5</sup> have been found of the same relative value for the chicken as irradiated ergosterol. Apparently the cow, as also very definitely the chicken,

does not change the biologic form of the vitamin when it makes the vitamin D available for the use of the offspring in the milk or the egg.<sup>6</sup>

Thus it is evident that at least two, and possibly only two, varieties of vitamin D exist. Purely laboratory products, formed neither in nature nor by the action of ultraviolet radiation, are not considered here. The products mentioned in the preceding discussion fall into two groups when considered in relation to their source. Those of animal origin are of one and equal value to the chicken; those of vegetable origin are of another value, also equal within the group. The differences between the two groups may depend on the relationship of vitamin D to cholesterol in one group and to ergosterol in the other group.

It is desirable to state that the relative position of "yeast milk" (milk from cows fed irradiated yeast) in the group of vitamin D materials named is not as clear as that of the other substances. Haman and Steenbock<sup>7</sup> found cod liver oil and also irradiated milk to be at least ten times as effective as "yeast milk." Bethke and his co-workers<sup>8</sup> found these materials to be "more than ten times" as effective as "yeast milk." In neither Bethke's nor Steenbock's experiment was the relative effectiveness of irradiated ergosterol determined. Older experiments indicate that the ratio of effectiveness of cod liver oil to irradiated ergosterol is 1:15 to 20 or more. No data have been found which permit a direct comparison of "yeast milk" with either irradiated ergosterol or irradiated yeast. In his paper Bethke states his belief that "yeast milk" is of the same value as irradiated yeast and elsewhere<sup>9</sup> he attributes the apparent discrepancy chiefly to the basal ration used.

Bills<sup>10</sup> has reported that the vitamin D of the liver oil of the blue fin tuna fish has for the chicken from one-sixth to one-seventh the potency of cod liver oil. Whether tuna liver oil contains a third variety of vitamin D is an unanswered question. Though an understanding of the problem raised by this observation is highly desirable, the finding seems to have no direct bearing on the evaluation of any of the vitamin D milks now produced and marketed.

#### APPLICATION TO MAN OF RESULTS WITH ANIMALS

No agreement has been reached concerning the relation of the human being to the rat and the chicken as regards reaction to vitamin D. Regardless of what may be this position, it would not be surprising to find that all vitamin D of animal origin has a similar potency and all vitamin D of vegetable origin another potency.

Let it be assumed for the purpose of illustration in discussion that the ratio of effectiveness of cod liver oil as compared to irradiated ergosterol on a rat unit basis is 1:1.5 for the human being; that all vitamin D of animal origin has the same value as cod liver oil, and that all vitamin D of vegetable origin has the same value as irradiated ergosterol. Such a relatively small difference may be difficult to detect by any but the most carefully controlled clinical experiments. If the minimum rickets-preventing intake of vitamin D of animal origin should be 70 units and that for vitamin D of

1. In all instances amounts of vitamin D are stated in terms of U. S. P. units (U. S. P. X Revised 1934).

vegetable origin 105 units, and if both vitamins D should be fed at a level of 105 units or more, the two products might appear to be of equal value, depending on the criteria used. Though the ratio of effectiveness and the minimum preventive doses stated may not be acceptable, the fallacy inherent in comparisons above the minimal effective level seems obvious unless the criteria of comparison extend beyond the mere prevention of rickets and include other factors influenced by vitamin D, which are discussed subsequently.

Accurate determinations of differences in vitamin D activity are associated with many difficulties even with the most rigid control possible with experimental animals. The difficulties are greatly increased in clinical studies; the differences in vitamin D activity apparently are much smaller, and strict control is not easily attained, especially in outpatient studies. Considering these factors and the individual variation among infants, it is not surprising that conflicting reports to the point of confusion have resulted from clinical experiments.

#### PREVENTIVE VERSUS CURATIVE STUDIES

Both preventive and curative studies are useful in comparing antirachitic agents. The presence or absence of rickets depends on the relative rate of growth and the intakes of calcium, phosphorus and vitamin D. In either a preventive or a curative study it is obvious that one cannot alter all these factors and still have a basis of comparison for one of them. In a curative experiment the time factor in healing and whether the healing is partial or complete are of especial importance. Bills<sup>11</sup> has shown that the time required for healing is not directly proportionate to the amount of vitamin D. In rats the production of 2 plus healing in three days requires 105 times and in five days 4.5 times as much vitamin D as is required to produce the same amount of healing in ten days. Apparently one may obtain a slight degree of healing with amounts of vitamin D smaller than a preventive dose. Bethke<sup>12</sup> has reported experiments wherein a degree of calcification was produced in rachitic rats from amounts of vitamin D insufficient for prophylaxis with the same diet. Russell,<sup>13</sup> as a result of experimental observations, states that "the unit or 1 plus level, determined curatively, affords only partial protection when fed on a preventive basis." It seems to require about 0.5 unit daily to prevent rickets in rats given the Steenbock diet 2965,<sup>14</sup> while it requires only about 0.27 unit daily for eight days to cause the amount of healing in ten days accepted as a standard in the Steenbock technic. However, it must be recognized that the minimum preventive dose and the dose which will produce ultimate complete healing may be the same, and that for rapid healing the dose must be larger than the preventive dose. It seems probable that, the greater the degree of rickets, the smaller the amount of vitamin D required to produce a slight degree of healing. Two plus healing is generally considered as representing a substantial increment of recalcification. This has not been found to be true for the rat.<sup>14</sup> Apparently 2 plus healing can occur with a bone ash increase of less than 1 per cent as compared to controls. If the same conditions hold for infants as have been found for rats as regards the correlation of the roentgenogram with the bone ash

increase, healing studies concern themselves largely with exceedingly variable and almost insignificant calcification, except when marked and rapid healing is recorded. All the factors enumerated make curative studies difficult to evaluate. For comparison it is essential that they be conducted with the various influencing factors on a common basis.

#### OUTPATIENT VERSUS INPATIENT STUDIES

Outpatient studies are necessary in order to obtain experimental material in volume, but such studies have inherent weaknesses which are difficult to overcome. Except for detection of gross differences, outpatient studies are rarely conclusive as regards quantitative comparisons. In inpatient studies the environment of all the infants is the same and presumably the intake of food of each infant can be more definitely determined and controlled than is possible even in a well conducted outpatient study. Certain types of quantitative study are possible only with inpatients.

#### QUANTITATIVE VERSUS QUALITATIVE STUDIES

The term quantitative as here employed implies the accurate measurement of a considerable number of factors related to the question to be answered by the experiment. These measurements in the case of vitamin D milk studies might include the intake of food and vitamin D, the body growth, periodic estimates of the calcium and phosphorus of the blood, and by balance studies the determinations of retentions of calcium, phosphorus and nitrogen. The inclusion of all these, especially of balance studies, limits greatly the number of children who can be observed at one time. Such studies are useful in determining trends, which serve as guides in the observation of larger and more loosely organized groups. It seems fair to state that each of the quantitative items mentioned adds to the ease of interpretation and therefore to the value of reported studies. In the review of the literature of vitamin D milks it was especially noticeable that chemical studies were a great aid in evaluating the clinical data. Serum calcium and phosphorus determinations are as valuable in preventive as in curative studies, though in each type of study some interpretation may be required. Chemical data constitute criteria that are wholly objective, whereas roentgenograms can be recorded satisfactorily in a publication only in terms of interpretation.

#### PREVENTION OR CURE OF RICKETS AS A CRITERION OF ADEQUACY OF VITAMIN D

Both the prevention and the cure of rickets may be used as criteria for comparing the relative efficacy of various forms of vitamin D. The trend of the literature, however, is to consider that the minimal amount of vitamin D which will prevent or ultimately cure rickets is an adequate amount for the infant. This concept is probably incorrect and may be considered as comparable to the conclusion that prevention of xerophthalmia is evidence of adequate intake of vitamin A. Evidence for this contention is presented in succeeding paragraphs.

#### THE RELATION OF VITAMIN D TO CALCIUM RETENTION

Criticisms of the utility of calcium retentions have been stated on the basis of wide variations shown by individual babies or even by the same babies on different occasions. It was pointed out by Stearns<sup>15</sup> that

the calcium retention by babies receiving little or no vitamin D has a wide range. Some retention is very good, other retention poor. As the intake of vitamin D is increased the average retention of calcium per kilogram is increased for any given per kilogram intake and the range of observed retentions narrows. The chief result of increased vitamin D seems to be in increasing the average level of retention of each infant to that of the best retention obtained without added vitamin D and in narrowing the range of retentions found. Thus it would seem that the range of variation is relatively narrow when effective amounts of vitamin D are given and that a wide range is characteristic of small or negligible amounts of vitamin D. When interpreted in the light of this discussion, balance experiments permit results which are reproducible with regularity.

A level of vitamin D which barely prevents rickets, such as vitamin D milk with 135 units to the quart, permits average calcium retentions definitely lower than those obtained with 400 unit milk or with one teaspoonful of cod liver oil.<sup>16</sup> If an amount of vitamin D which merely prevents rickets does not permit what are considered to be optimal retentions of calcium, rickets prevention cannot be accepted as a criterion of the adequacy of vitamin D intake. The difficulty here lies in the incomplete knowledge of what constitutes an optimal retention. However, probably few physicians would consider that any retentions obtained with one teaspoonful of cod liver oil daily are excessive; the amount of cod liver oil which prevents rickets seems to be approximately one third of this amount. Actual retentions with these amounts of vitamin D are stated subsequently.

#### THE RELATION OF VITAMIN D TO GROWTH

A certain few nutritional essentials have acquired the designation of "growth promoting." It is well recognized, however, that growth is retarded by deprivation of several materials not commonly designated in this fashion. The importance of calcium in growth has been demonstrated abundantly for animals.<sup>17</sup> To the extent that this finding applies to the human being and to the extent that vitamin D aids in calcium utilization, vitamin D is important for growth. Little has appeared in the literature concerning the relation of calcium to growth in man. Two reports by Jeans and Stearns<sup>18</sup> suggest the possibility that such a relationship exists. Daniels and her co-workers<sup>19</sup> found that infants receiving cod liver oil had a greater rate of growth than infants receiving the same diet without cod liver oil; the increased growth was attributed to vitamin D rather than to vitamin A. If a relationship actually exists between growth and vitamin D and if the amount of vitamin D which barely prevents rickets does not permit excellent growth, rickets prevention cannot be accepted as a criterion of adequacy of vitamin D intake.

It seems probable that a fallacy exists in considering growth as excellent when it merely falls within the limits of average growth by the usual standards such as those of Stuart or Kornfeld. Averages are made

up of data from children who have received good, poor and indifferent nutritional care. Normal or excellent growth should be judged on the basis of what children will do when the nutritional factors that promote growth are favorable. The question as to whether growth curves at the upper limits of the average range represent really superior or optimal growth is not easily answered, but at least it is reasonable to think of it as superior on the basis of the factors mentioned in this discussion. One of the conclusions reached by Daniels<sup>19</sup> in a growth study is that the accepted standards of growth for infants are too low.

#### THE DIAGNOSIS OF RICKETS

Very brief reference to the literature<sup>19</sup> is all that is necessary to show that the clinical diagnosis of rickets (without roentgenograms) is unreliable and that great disagreement exists between the clinical diagnoses of various observers as well as between the clinical and roentgenographic diagnoses of the same observer. Logic favors the view expressed by Eliot,<sup>20</sup> who stated that "doubt is thrown on the reliability of clinical diagnoses of mild rickets in the absence of roentgenographic evidence of the disease." It would seem safe to take the stand that the clinical diagnosis of slight or mild rickets is not acceptable as evidence of this disease.

Reference to the literature<sup>19</sup> also makes obvious the conclusion that the criteria of roentgen diagnosis are not the same among those conceded to be expert in this field. A contrast is to be noted between Hess's 15 per cent incidence of rickets in a group selected at random and the 63 per cent or more in Eliot's group under good care and receiving vitamin D from two sources.

In further illustration of the variation in interpretation of roentgenograms of epiphyses of infants by different observers, the following experience is cited:<sup>21</sup> A series of roentgenograms of the wrist of each of twenty-five infants was used as the basis of an inquiry. This series of roentgenograms was obtained from three groups of infants who had been studied quantitatively; the intakes of milk and of vitamin D were known, the calcium and phosphorus retentions had been studied throughout the major part of infancy, the levels of calcium and of phosphorus in the serum had been determined at intervals, and accurate records had been kept of growth, dentition and motor achievement. The infants of groups 1 and 2 had been given whole acidified fresh or evaporated milk respectively and had received 340 units of vitamin D daily (an average of 50 units per kilogram), together with orange juice, sieved vegetables and fruits. The babies of group 3 received the same foods as those of the first two groups but only from 60 to 135 units of vitamin D a day (an average of 15 units per kilogram).

The serum calcium and phosphorus values in all three groups were normal; i. e., calcium was always above 10 mg. and phosphorus always above 5 mg. per hundred cubic centimeters. Each infant in groups 1 and 2 grew both in length and in weight at greater than the average rate; dentition was early, most of the infants having cut two teeth by 6 months of age and six teeth by 9 months of age. No infant attained the age of 8 months without having cut at least two teeth. Carpal centers became visible to the x-rays more rapidly than

is usual. The infants were physically very active. The majority were able to sit unsupported by 6 months of age and could pull themselves to standing by 9 months. In short, the infants of these two groups were superb physical specimens. The retentions of calcium, phosphorus and nitrogen were very high, indicating that, notwithstanding the rapid growth, the mineralization of bones and the muscular development were above the average.

The rate of growth of the infants of group 3 was much slower than that of the babies in the other two groups, although it could be considered "average." Dentition was late; most of the infants did not begin cutting teeth until 8 or more months of age. None of these infants were able to sit unsupported at 9 months of age; two were able to do so by 10 months, but the muscles were flaccid and the posture poor. The retention of calcium and phosphorus by the babies of this third group was much less than in the babies of groups 1 and 2; so much less that the slower rate of growth did not compensate, and the retention per kilogram of weight increase and per centimeter of growth in length was definitely lower than the retention for the babies of groups 1 and 2.

The investigators who examined the roentgenograms of the wrists of the babies of these three groups included two who are expert in reading roentgenograms of infants, two heads of roentgenology departments in medical schools and an orthopedic surgeon experienced in reading roentgenograms of bone. All observers agreed that no infant in group 3 showed any evidence of rickets. One of the two experts and the orthopedic surgeon found no evidence of rickets in any of the roentgenograms in either group 1 or group 2. The

other observers each found evidence of slight rickets in both groups 1 and 2. In fact, each infant in these two groups was diagnosed as rachitic at some time during the period of infancy by at least one person. Rarely did two people agree as to the period of rickets. In view of the chemical data and growth and achievement records of these three groups of babies, it is surprising to find the interpretation of rickets in the babies of groups 1 and 2 and of no rickets in those of group 3. For the purpose of illustration, chemical data obtained from two infants of groups 1 and 2 are presented here, together with average data obtained from the studies

of the babies of group 3. The infants cited were each typical of the infants of their groups; they are chosen because of the definite diagnosis of rickets made by an expert observer. For the sake of brevity only calcium retentions are stated; phosphorus retentions corresponded to the expected values as calculated from the calcium and nitrogen retentions.

five day period, which includes the time of the diagnosis of rickets, he retained more total calcium per kilogram and per centimeter of growth than did the babies of group 3 considered in the same age period. His serum calcium and phosphorus values were slightly higher than those of group 3. He received more vitamin D in his food and in addition received an abundance of sunlight during the time that "rickets" developed. He had cut three teeth at 22 weeks and sat alone at 25 weeks of age. Despite all these indications of good growth he had what was termed rickets, whereas the babies of group 3 with poorer retention for each unit of growth and poorer physical development had no rickets.

In the roentgenograms of those diagnosed as having slight rickets, something definite is present which differs from the appearance of roentgenograms usually classed as normal. Various observers interpret these changes differently and thus may be explained the differences in reported readings. The changes in the roentgenograms, though slight, are readily demonstrable and are identified repeatedly and without confusion by the same observer in a long series of examinations. These changes appear in the roentgenograms of babies receiving little or no vitamin D, tend to be absent in those of babies receiving moderate amounts of vitamin D, and appear in those of babies receiving an abundance of vitamin D. In the babies receiving little or no vitamin D and who are developing rickets as shown by later observation, the changes are the precursors of those which characterize unmistakable rickets. When they appear in babies who are receiving an abundance of vitamin D and who have high retentions of calcium and phosphorus, they obviously cannot represent the early stages of rickets but may be merely concomitants of rapid normal growth.

On the basis of these premises the diagnosis of slight rickets has been disregarded in the interpretation of the studies of this review. If the premises are unacceptable, the diagnosis of slight rickets must be disregarded in order to bring the various reported studies onto a more common ground for comparison.

## THE FREQUENCY OF SMALLPOX AND SMALLPOX VACCINATION

Reasonably accurate data are now available from which it is possible to make a rough estimate of the extent of vaccination in the United States. A nationwide survey,<sup>1</sup> which included 9,000 families in 130 localities in eighteen states, was made over a twelve months period. Thirty-nine thousand persons in every size of community were represented in the group. While it is natural that the statistics resulting from this study cannot be projected to the whole population, a definite effort was made to have the group entirely representative in all factors. The proportion of persons of different ages who gave a history of vaccination within seven years of the date of interview varied, according to Collins, from a maximum of 60 per cent at 10 years of age to 23 per cent at 20 to 24 years and 16 per cent at 25 to 34 years. The decline occurred at a less rapid rate thereafter. It was thus indicated that only perhaps 10 per cent of the people were revaccinated at intervals of seven years or less and that the great majority of children vaccinated at the time of entrance into school were never revaccinated. When all ages were considered, 56.9 per cent of the males and 57.9 per cent of the females gave a history of vaccination or of having had smallpox at some time in their lives. Three and 3.2 per cent respectively gave a history of a previous attack of the disease. In the rural areas included in the survey slightly more than 40 per cent of the adults gave a history of vaccination. In the cities with populations of 100,000 or more about 85 per cent of the adults had been vaccinated. Smaller cities and towns fell in between these two groups. The expected corollary with regard to the number of cases of smallpox was observed. Thus, 1.5 per cent of persons of all ages living in cities of more than a hundred thousand had a history of having had smallpox. In the towns under 5,000 and in rural areas there was a history of smallpox in 4.3 per cent. There is hence not so great a difference as might be expected from the

vaccination statistics, the explanation for which might be the relatively less frequent contact and possibly the greater frequency of cowpox in the farm population.

The eighteen states in which the surveyed population lived was divided into four geographic sections: the Northeast, the North Central, the South and the West. The Northeast appeared to be less well vaccinated than the other sections, but this conclusion is not necessarily statistically representative, since in some geographic sections many cities were included in the surveyed sample and in others the sample was more largely rural.

The record of all medical care, whether for illness or for preventive service, affords accurate data on the frequency of vaccinations during the twelve months of the morbidity study. The record for one year, however, although more accurate than the historical material, might indicate more frequent or less frequent vaccinations than the average over a period of years. Those vaccinations which were performed during this period were largely concentrated in a few communities. Twelve communities, or 10 per cent of the 119 localities, including 9 per cent of the surveyed families, contributed 74 per cent of vaccinations during the year. The other 26 per cent of vaccinations were done in fifty-five communities. Forty-four per cent of the communities, including 30 per cent of the families, contributed no vaccinations during the studied year. The twelve localities that contributed nearly three fourths of the vaccinations were all classed as having epidemics or threatened epidemics during the observation year. Thus, in the nine communities with the largest numbers of vaccinations in which smallpox was epidemic in the county, the vaccinations were highly concentrated in the same months in which the largest numbers of smallpox cases were reported. It is clearly indicated, therefore, that the presence of smallpox supplies a powerful motive for vaccination.

The vaccinal status of families attacked by smallpox was especially interesting. Of the sixty-seven persons in the fourteen households attacked during the twelve months study, forty-eight, or 72 per cent, had never been vaccinated or had previous smallpox. This compares with 43 per cent unvaccinated in the whole surveyed group. Twelve persons, or 18 per cent, had been vaccinated at some time; in ten of the twelve the vaccination was more than seven years previous to the study. Ten per cent had suffered attacks of smallpox prior to the study, but five of the seven cases of this group were in one family. Of the thirty-one children under 15 years of age in attacked households, none had been vaccinated. This compares with 41 per cent vaccinated in the whole surveyed group. The data suggest that the households which were attacked by smallpox during the study period had less vaccinal protection and more previous smallpox than the average for the whole surveyed group. There were seventeen cases of smallpox in the whole surveyed population, which is at an annual case rate of 44.1 per hundred

1. Collins, S. D.: History and Frequency of Smallpox Vaccination and Cases in 9,000 Families, Pub. Health Rep. 51: 443 (April 17) 1936.

thousand persons, as compared with a reported average annual rate for the United States of 37.1 for the years 1929 to 1930, a period approximating that covered by the survey. Sixteen of the seventeen cases occurred in persons with no history of vaccination or previous attack. This is a rate of 96 per hundred thousand of population, as compared with a rate of 5 per hundred thousand among persons previously vaccinated or immunized by attack. Since there were no smallpox deaths among these seventeen cases, the mortality data for the general population were used. In the continental United States there were 91,189 cases of smallpox reported in 1929 and 1930, an annual incidence rate of 37.1 per hundred thousand. The total of 347 deaths registered gives an annual mortality of 1.41 per million and a case fatality of 0.38 per cent. Evidently smallpox was not extremely malignant during these years.

The survey reported by Collins is especially significant in its indication that even now a relatively large proportion of the population is unvaccinated and that a further large number have had an insufficient number of revaccinations. The apparent present mildness of smallpox does not insure the permanent disappearance of the malignant variety, especially if any further increase in the nonimmune population occurs. Furthermore, an annual incidence rate of smallpox of 37.1 per hundred thousand, even when accompanied by a low mortality is, in view of the effectiveness of immunizing measures, a sufficient indication for unceasing vigilance and activity.

### SUNLIGHT AND HEALTH

The belief that sunlight exerts a beneficial effect on health is at present exceedingly popular. Its general endorsement by the public is visible during the summer months at the beaches and summer resorts. The growing tendency to continue "sun bathing" throughout the year is indicated by the increasing numbers of "sun lamps" available on the open market and the rather large numbers of these devices purchased by the American people for use in their homes. But what is the scientific knowledge regarding the effects of sunlight and of ultraviolet rays on health? Does such information indicate a need for excessive basking in the sun's rays or does it suggest that this practice is unnecessary or perhaps even undesirable? Laurens<sup>1</sup> has recently reviewed the available knowledge in this field.

First, which of the sun's rays actually pass through the outer layer of the skin into the deeper strata? Studies have shown that practically all the rays in the extreme ultraviolet range are reflected from or absorbed by the outer, horny layer of the skin, whereas a considerable proportion of the longer ultraviolet, the visible and the near infra-red rays are transmitted and

penetrate into the malpighian layer, the corium and, in the case of the visible and near infra-red rays, even the subcutaneous tissues. Thus, the horny layer of the skin apparently protects the deeper strata from the shorter ultraviolet rays. Pigment, which is present in the basal layer of cells of the stratum corium, apparently serves as a screen to prevent the "true skin" from receiving too much energy in the form of the longer ultraviolet rays.

The question of the effects of the rays that are transmitted by the stratum corneum into the deeper layers of the skin has received wide attention. Certain beneficial effects are well known, as, for example, the favorable influence of the ultraviolet rays on the assimilation of calcium and phosphorus and the resultant prevention or cure of rickets as the result of the formation of vitamin D in the skin. Favorable effects of moderate amounts of sunlight on the blood and circulation have also been described, particularly in increasing the platelet count in cases of idiopathic purpura haemorrhagica and as an adjuvant to diet and standard therapy in the treatment of secondary anemia. "Sunshine" carbon arc radiation has been alleged to cause a temporary decrease in both the systolic and the diastolic blood pressure in patients with essential hypertension. Natural sunlight, according to a number of authorities, hastens the healing of sluggish, indolent wounds by its local effect on the circulation of the blood and may be of benefit in tuberculosis of the skin (*lupus vulgaris*). Many believe that heliotherapy constitutes a valuable aid in the treatment of pulmonary tuberculosis. However, perhaps as many equally competent authorities feel that the results are "not likely to be spectacular and its omission not detrimental to the patient's best interest."

Harmful as well as beneficial effects may result from exposure to sunlight. Under certain conditions, as yet none too well defined, photosensitization may occur and the subject so sensitized may experience serious reactions on subsequent exposures to sunlight. A number of skin diseases, such as *urticaria solaris* and *lupus erythematoses discoides*, are probably due to this type of sensitization. Likewise it is well known that prolonged exposure to sunlight may cause not only inflammatory and degenerative changes in the skin but also systemic disturbances. One authority has stated that overexposure to sunlight may bring about damage to the central nervous system, especially the brain, as a result of heating of the skull.

Thus it is evident not only that sunlight may exert a beneficial influence on health but also that it may cause serious harmful effects. Laurens believes that the beneficial effects appear to be largely overemphasized. As far as is known, man actually requires only a relatively small amount of sunshine for the maintenance of normal health, and the greatest danger perhaps at the present time lies in too much exposure to sunlight rather than too little. Certainly, overindulgence in solar radiation should be avoided because of known possible

<sup>1</sup> Laurens, Henry: *Sunlight and Health*, *Scient. Monthly* 42: 312 (April) 1936.

ill effects. "Owing to the hypersensitivity of many infants and adults, caution should be used in the use of sunlight, both natural and artificial. Overindulgence, even in the normal, is foolhardy."

### THE DANGERS OF VENTRICULOGRAPHY

Ventriculography is defined by Pendergrass<sup>1</sup> as a procedure in which a series of roentgenograms is made of the head in several positions in the horizontal posture within one hour following the removal of all the available cerebrospinal fluid from the ventricles of the brain and its replacement by air. Since the procedure was first described by Dandy in 1918 a voluminous literature has developed, the general trend of which has been to stress the diagnostic value of ventriculography and to minimize the dangers. Several writers have pointed out complications that may follow ventriculography. At the Neurological Institute of New York a study of the dangers and mortality of ventriculography was made covering the five year period that ended with 1932. Riggs<sup>2</sup> says in the report of this study that ventriculography was performed 148 times for suspected brain tumors. During the first two years the posterior horn of one ventricle was punctured, the fluid was withdrawn, and then air was injected. Later Frazier's method was followed, whereby bilateral trephine openings were made, a needle was introduced into each posterior horn and air allowed to enter the ventricles as the fluid was evacuated by turning the head in various directions. During the last two years of the five year period changes were made in the site of the trephine openings, according to the technic described by Deery.

The most common mild symptoms that followed ventriculography in the 148 cases were headache, nausea, vomiting, and some rise in temperature. The dangerous symptoms that frequently followed consisted of stupor in forty-three cases, and changes in respiration, pulse, blood pressure and temperature; twelve of these patients died. In the fatal cases there was usually a progressive stupor, with a terminal rise in temperature to about 107 F. Three patients died of acute respiratory failure, one being kept alive for several hours by artificial respiration. The onset of the stupor varied from immediately after the ventriculography to the third day. The dangerous symptoms that developed usually appeared within the first ten hours, but in the patients who succumbed following ventriculography the dangerous symptoms began within the first eight hours in most of the cases. The forty-three patients who developed dangerous symptoms, including the twelve who died, comprise two groups: (a) those who were acutely ill with advanced signs of brain tumor and were stuporous before the introduction of air and (b) those

who were not stuporous and were generally in fair condition before ventriculography was performed. Of the twelve patients who died, eight belonged to the second group; of the thirty-one patients who had dangerous symptoms but recovered, twenty-three belonged to the second group.

Fatalities following ventriculography, the New York investigators concluded, are usually due to the profound effects on the pressure conditions within the cranial cavity of the removal of fluid and the introduction of air and are rarely due to hemorrhage into the ventricles. There is a delicate balance, they say, in most instances, and particularly in subcortical growths, in the pressure conditions within the cranial chamber, which is profoundly disturbed when fluid is removed and air allowed to enter the ventricles. Ventriculography is especially dangerous in patients having subcortical tumors located deep enough to make pressure on the third ventricle and the brain stem. Furthermore, the relations of the various parts of the brain to one another are probably altered during the evacuation of fluid and the entrance of air into the ventricles. The report of this investigation seems to show that death or dangerous symptoms occurred less often when one trephine opening was made and when fluid was removed gradually and air injected slowly.

In the treatment of the forty-three patients who developed dangerous symptoms after ventriculography, the use of caffeine and hypertonic dextrose solution intravenously was rarely of any benefit; among those who died, puncture of the ventricle to evacuate the air had practically no beneficial effect. However, in 78 per cent of the patients who had dangerous symptoms but recovered there was a definite beneficial effect from the release of the air in the ventricles. The major operation for the brain tumor probably should follow the ventriculography just as soon as the x-ray films have been developed and a decision has been made as to the location of the tumor. This rule has been adopted in many neurologic clinics.

Masson<sup>3</sup> reported another study from the Neurological Institute of New York concerning the disturbances in vision after ventriculography. Six cases of temporary blindness occurred among 100 consecutive cases. One of these patients had reduction in visual acuity before the ventriculography, but the other five patients had either normal or slightly reduced visual acuity before the ventriculography. The vision of all these six patients, however, was regained in from twenty-one to seventy-two hours. Four of them were operated on during the blind period and the loss of sight in them averaged forty-five hours; in two patients who were not operated on during the blind period, the blindness lasted twenty-one and twenty-six hours. Masson and his associates offer no satisfactory expla-

nation for the temporary blindness, but believe it was in some way connected with the puncture of the brain.

Since practically all patients with brain tumors die unless operated on, and since location of the tumor is essential to proper operative procedures, ventriculography is in some cases an indispensable diagnostic procedure. It should be used, however, only in patients in whom localization of the tumors is impossible by clinical means, and special care should be taken in patients whose tumor is causing pressure on the third ventricle or the brain stem.

## Current Comment

### OXYGEN AND SEIZURES OF EPILEPSY

In the majority of patients having frequent attacks of petit mal, seizures can be consistently induced by anoxemia. Analyses of the respired air of epileptic patients during an attack have shown that the oxygen content is decreased from the normal of approximately 14 per cent to from 8 to 12 per cent. Unconsciousness occurs in normal persons when the oxygen content is reduced to about 7 per cent. As a low oxygen tension precipitates seizures in epileptic patients, a high oxygen tension might prevent or at least lessen the frequency of attacks. This possible effect of oxygen has been recently subjected to experimental study.<sup>1</sup> The patients used for the investigation were three young women who were having numerous attacks of petit mal daily and with whom experience over a period of years had demonstrated that seizures invariably followed either the breathing of an oxygen-poor mixture or hyperpnea. The patients, along with the observers, were placed in a gas-tight chamber and were subjected to pressures ranging up to 4 atmospheres for periods of from three and one-half to five hours. The number of attacks of petit mal which occurred during these periods were compared with those during an equal interval on the same day while the patients were exposed to normal atmospheric pressure. The data thus obtained showed that the number of spontaneous attacks was decreased an average of 45 per cent during the periods of increased pressure. Similar results were obtained in studies on the effect of increased oxygen tension on seizures induced by hyperpnea. As the pressure of oxygen was increased in the inspired gas mixture, the time required for the precipitation of a seizure was correspondingly increased. In one patient a twenty-fold increase in oxygen tension resulted in a fivefold increase in the amount of overventilation required to produce an attack. These observations seem to indicate a distinct relation between the oxygen content of respired air and seizures of petit mal. The exact nature of this relation is as yet not known but it is possible that some alteration of the acid-base balance of the blood is involved. It is well known that patients remain seizure free while in a state of acidosis and perhaps the administration of oxygen under the conditions employed may have favored the development of a similar condition.

1. Lennox, W. G., and Helmke, A. R.: Effect of Increased Oxygen Pressure on the Seizures of Epilepsy, *Arch. Neurol. & Psychiat.* 25: 782 (April) 1936.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### CALIFORNIA

**Noise Abatement Committee.**—Mayor Rossi has appointed a committee of physicians, engineers, lawyers, civic organization officials and other lay persons to study noise abatement in San Francisco. The department of health of San Francisco, working through its division of industrial hygiene, has made certain recommendations to the newly appointed committee, following a two weeks intensive survey with special noise detecting instruments.

**Low Infant Mortality Rate.**—California recorded the lowest infant mortality rate on record in 1935, 49.5 per thousand live births. Of 3,973 infant deaths recorded, 2,546 were among white infants, giving a white infant mortality rate of 39.5. On the other hand, there were 1,184 deaths of Mexican infants recorded, giving a racial infant death rate of 100.7. Ten per cent of Mexican infants born in California last year died during the first year of life, while less than 4 per cent of white infants died during the first year of their existence, according to the state health department.

**State Medical Election.**—Dr. Howard Morrow, San Francisco, was chosen president-elect of the California Medical Association at the recent meeting in Coronado, and Dr. Edward M. Pallette, Los Angeles, was installed as president. The next annual session of the association will be held in Del Monte. A resolution was passed opposing the opening of county hospitals to nonindigent persons. It is expected that an initiative measure authorizing this extension of hospital service will appear on the ballot in the November election. The association also took the position that roentgen technic, including laboratory services, constitute medical service and therefore should be under the control of the medical profession.

**Public Health in University Program.**—At the Institute of Government, June 15-19, sponsored by the University of California at Los Angeles, the program for the public health section, under the direction of Ira V. Hiscock, C.P.H., professor of public health, Yale University School of Medicine, New Haven, will include the following speakers:

- Dr. Hiscock, Trends in Public Health and Methods of Measuring Needs and Effectiveness of Public Health Service.
- Dr. Fred T. Foard, San Francisco, regional consultant, U. S. Public Health Service, The Social Security Act and Public Health.
- Dr. Edith P. Sappington, San Francisco, regional consultant, Children's Bureau, The Social Security Act and Maternity and Child Hygiene.
- C. V. Duckworth, assistant director, state department of agriculture, Bovine Tuberculosis and Undulant Fever.
- Dr. Jacob C. Geiger, health officer of San Francisco, Milk Inspection.

### CONNECTICUT

**State Medical Meeting and Election.**—Dr. Daniel C. Patterson, Bridgeport, was elected president of the Connecticut State Medical Society at its annual meeting in Hartford, May 20-21. Vice presidents are Drs. Thacher W. Worthen, Hartford, and Hugh B. Campbell, Uncas-on-Thames, Norwich, and the treasurer is Dr. James R. Miller, Hartford. It was agreed to establish a full time office for the society in New Haven, to be under the direction of Dr. Creighton Barker as administrative secretary. Dr. Charles W. Comfort Jr., New Haven, under the new arrangement becomes legislative secretary, and Dr. Stanley B. Weld, Hartford, secretary on scientific work. Dr. Weld will also be editor of the quarterly bulletin now planned by the society. The address of the new office is 258 Church Street, New Haven, and Miss Margaret Capello is the secretary. Out of state speakers on the program included:

- Dr. Adrian S. Taylor, Clifton Springs, Clinical Aspects of Thyroid Disease.
- Dr. Stafford L. Warren, Rochester, N. Y., Results of Comparative Doses on Human Tumors Using Fever and Roentgen Radiation.
- Dr. Emil Novak, Baltimore, Use and Abuse of Endocrinology in Gynecology.
- Dr. Arthur P. Noyes, Howard, R. I., Relationship of Psychiatry to Medicine.
- Dr. George C. Andrews, New York, Pastular Bacterids of the Hands and Feet.
- Dr. Conrad Berens, New York, Clinical Considerations of Ocular Fatigue.
- Dr. Eliezer Ross Faulkner, New York, Review of Operative Technic in Nose and Throat Surgery.

## DELAWARE

**Medical Art Exhibit.**—The Delaware Academy of Medicine participated in the second annual Delaware Art Week, May 3-10, in Wilmington, by displaying in the library an exhibit showing "Art as Applied to Medicine."

**Health at Wilmington.**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended May 30, indicate that the highest mortality rate (17.7) was for Wilmington. For the group of cities as a whole it was 10.9. The mortality rate for Wilmington for the corresponding period last year was 10.8 and for the group of cities, 11.5. The annual rate for eighty-six cities for the twenty-two weeks of 1936 was 13.3 as against a rate of 12.4 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

## DISTRICT OF COLUMBIA

**Medical Bills in Congress.**—S. 4195 has passed the Senate, directing the Commission on Licensure to Practice the Healing Art to issue a license to Dr. Ralph Charles Stuart. A similar House bill, H. R. 11695, has been favorably reported to the House.

**Society News.**—The Washington Ophthalmological Society was addressed, May 4, among other speakers, by Deane B. Judd, Ph.D., of the National Bureau of Standards on "Color Blindness and Anomalies of Vision" and Major Raymond O. Dart of the Army Medical Museum on "Ocular Tumors."

## FLORIDA

**Society News.**—Dr. Kenneth A. Morris, Jacksonville, addressed the Duval County Medical Society, May 5, on "Surgery in the Treatment of Pulmonary Tuberculosis."—At a meeting of the Lake County Medical Society, April 3, Dr. Spencer A. Folsom, Orlando, discussed hyperinsulinism.—The Pinellas County Medical Society was addressed in St. Petersburg, May 1, by Dr. George E. Miller, on influenza. Dr. Orville N. Nelson, Bay Pines, discussed head injuries before the society, May 15.

## GEORGIA

**Personal.**—Dr. William D. Jennings Jr., Augusta, has been appointed to the newly created position of police and fire surgeon.

**Society News.**—The Fulton County Medical Society was addressed in Atlanta, June 4, by Drs. Allen H. Bunce on "Diagnosis and Medical Treatment of Gallbladder Disease"; John Shelton Horsley, Richmond, Va., "Surgical Aspect of Cancer," and Roy R. Kracke, Emory University, "Leukopenic Diseases." Dr. Horsley also addressed the second anniversary meeting of the Atlanta Cancer Clinic at the Georgia Baptist Hospital, June 4-5.—At a meeting of the Second District Medical Society in Quitman, April 10, speakers included Drs. John C. Keaton, Albany, on "Transurethral Prostatic Resection"; William G. Hamm, Atlanta, "Harelips and Cleft Palates," and Henry M. Moore, Thomasville, "Tobacco Amblyopia."—The Colquitt County Medical Society was addressed in Moultrie, April 7, by Dr. James A. Redfern, Albany, on "Electrocardiograph and Its Use in the Diagnosis of Various Heart Conditions," and Dr. Thomas H. Chesnutt, Moultrie, diphtheria.—A symposium on infections of the genito-urinary tract was presented before the Coffee County Medical Society in Douglas, April 28, by Drs. Bascom O. Quillian and Thomas H. Clark, both of Douglas.—Dr. Job C. Patterson read a paper before the Randolph County Medical Society in Cuthbert, May 7, on "Abdominal Pain—Differential Diagnosis."—Among others, Dr. Everett L. Bishop, Atlanta, addressed the Macon Medical Society of Bibb County, April 7, on "Bone Tumors and Their Treatment by Radiation or Surgery." Dr. Robert C. Goolsby Jr., Macon, addressed the society, May 7, in Macon, on "Care of the Sick and Injured in Storm Devastated Areas."

## IDAHO

**Annual Registration Due July 1.**—All practitioners of medicine and surgery holding licenses to practice in Idaho are required by law to register annually on July 1, with the department of law enforcement, and at that time to pay a fee of \$2. If a licentiate has not paid the annual registration fee by October 1, his license can be canceled but will be restored

within five years thereafter on payment of the delinquent fees and a \$10 penalty. If a license has been canceled for more than five years, it can be reinstated only on the payment of \$25 and on the licentiate's passing an examination, the nature of which shall be determined by the department of law enforcement.

## ILLINOIS

**State Medical Election.**—Dr. Rollo K. Packard, Chicago, was named president-elect of the Illinois State Medical Society at its recent annual meeting in Springfield, and Dr. Rolland L. Green, Peoria, was installed as president. Vice presidents are Drs. Richard F. Herndon, Springfield, and John W. Long, Robinson; Drs. A. J. Markley, Belvidere, and Harold M. Camp, Monmouth, are treasurer and secretary respectively. The next annual session will be held in Peoria.

## Chicago

**Personal.**—Dr. Walter Wile Hamburger has resigned as clinical professor of medicine at Rush Medical College, University of Chicago, effective July 1.—Dr. G. Howard Gowen has been appointed assistant epidemiologist to the state department of health, effective July 1.

**Bust of Dr. Carlson Unveiled.**—A bust of Dr. Anton J. Carlson, professor and chairman of the department of physiology, University of Chicago, was unveiled, June 1, in the hall of the physiology building, the gift of friends and students of Dr. Carlson. The bust was presented to the university by

Dr. Arno B. Luckhardt, also professor of physiology at the school, and Frederic C. Woodward, LL.D., vice president, gave the speech of acceptance. Dr. Carlson was born in Sweden in 1875. He came to America in 1891, taking his degree of doctor of philosophy at Leland Stanford University in California, in 1902. After two years of teaching and research at Stanford and Carnegie Institution he joined the University of Chicago in 1904 as assistant professor of physiology and in 1914 was made professor. In 1929 he received the title of

Frank P. Ilion distinguished service professor. Dr. Carlson's research has included among others the following subjects: rate of conduction of the impulse in nerves; the nature of the heartbeat; lymph formation and salivary secretion; comparative physiology of the circulation; comparative physiology of the thyroid and parathyroid; physiology of the alimentary tract and of the visceral sensory nervous system.

## INDIANA

**Child Health.**—A new program of child health is to be instituted in public schools of the state as a part of Indiana's activities in connection with the federal government's social security plan. Dr. Thurman B. Rice, assistant director of the state health department, will be in charge of the program, with the title of director of physical and health education.

**Changes in Health Officers.**—The monthly bulletin of the Indiana Division of Public Health announces the following changes in health officers:

Dr. Elmer D. Johns, Zionsville, succeeding Dr. Lawrence S. Bailly as town health officer.  
Dr. Camden G. Bothwell, Martinsville, succeeding Dr. George B. Breedlove as health officer of Morgan County.  
Dr. James L. Denaut, health officer of Hamlet.  
Dr. Clyde J. Munns, Newburgh, succeeding Dr. John T. Samples as health officer of Warrick County.

**Physicians Honored.**—Drs. William N. Wishard, professor and head of the department of genito-urinary surgery, and Charles E. Ferguson, emeritus professor of obstetrics, Indiana University School of Medicine, Indianapolis, were guests of honor at a banquet, April 29, given by the Pi chapter of Phi Rho Sigma Fraternity. They are the oldest alumni of the local

chapter of the fraternity, Dr. Wishard having graduated from Indiana Medical College in 1874 and Dr. Ferguson in 1892. Dr. Wishard, 84 years old, is still in active practice and Dr. Ferguson, now 79, retired from teaching in 1920. Dr. Roscoe L. Sensenich, South Bend, president of the state medical association, gave an address at the banquet, and Dr. Ezra Vernon Hahn, Indianapolis, was toastmaster.

**Resolution on Change in Control of Veterans' Medical Service.**—Members of the Wade H. Williamson Post, number 241, American Legion, Patriot, recently adopted a resolution urging that the present system of handling veterans' affairs through the Veterans' Administration be replaced by a pension system with local examining boards as the basic unit. The resolution recommends that all money expended by the federal government for hospitals or for hospitalization be given for the maintenance and support of local hospitals or paid in cash for the disabled veteran, and that he be allowed his constitutional right to select the hospital and physician of his own choice and pay his own bill. The resolution, submitted by Dr. Miles F. Daubenheyer, suggests that these examining boards be composed of three physicians with one lay member to determine the nature and degree of disability of veterans.

### IOWA

**Tribute to Physicians.**—Drs. William Jepson and Frank J. Murphy, Sioux City, were guests of honor at a dinner meeting of the Woodbury County Medical Society, May 26. Dr. Jepson, who has completed fifty years in the practice of medicine, was presented with a watch. Dr. Murphy is now in his fiftieth year of practice. Dr. Charles T. Maxwell, Sioux City, president of the county medical society, presided, and speakers included the following physicians: Kellogg Speed, Chicago, who discussed fractures of the spine, and William R. Whiteis, Iowa City; Peter H. Salter, Norfolk, Neb.; Joseph C. Ohlmacher, Vermillion, S. D.; Edward M. Myers, Boone; Howard L. Beye, Iowa City; Ewen M. MacEwen, Iowa City; Walter L. Bierring, Des Moines, and Prince E. Sawyer, Sioux City.

**Society News.**—The Des Moines Academy of Medicine and Polk County Medical Society were addressed, May 26, by Drs. Arthur W. Erskine, Cedar Rapids, on "Cancer Survey in Iowa"; Lester G. Erickson, Dubuque, "Early Recognition of Carcinoma of the Stomach," and Alva P. Stoner, "Rôle of Fibrous Tissue in the Repair of Hernia, with Special Reference to Injection Therapy."—Dr. Alice M. Humphrey Hatch, Des Moines, was chosen president of the State Society of Iowa Medical Women at its annual meeting. Life memberships in the society were conferred on the following physicians: Sophie H. Scott, Nello P. S. Noble, Jeannette Dean Throckmorton, Leone Morden Scruby, all of Des Moines; Eppie S. McCrea, Eddyville; Emma Jewel Neal, Cedar Rapids; Jane D. McIntosh Wright, Clear Lake; Rosabell A. Butterfield, Indianola; Mary K. Heard, St. Petersburg, Fla., and Pauline M. Leader, Clarinda.—Dr. Robert Q. Rowse, Sioux City, was elected president of the Iowa Clinical Surgical Society, April 25.

### KANSAS

**Fifty Years of Practice.**—Drs. William E. Ham, Beattie, and Robert Hawkins, Marysville, were guests of honor at a dinner given by Dr. John W. Randell at his home in Marysville recently in recognition of their completion of fifty years in the practice of medicine. Dr. Hawkins was unable to be present on account of illness in his home. Speakers in a symposium on tuberculosis were Drs. Harold E. Petersen, Earl M. Shores and Jacob Kulowski, St. Joseph, Mo. Dr. Ham graduated from Rush Medical College in 1882 and Dr. Hawkins in 1885.

### KENTUCKY

**Personal.**—Dr. Alfred F. Smith, Georgetown, has been appointed health officer of Greenup County, succeeding Dr. Carl M. Gambill, who held the position three years.—Dr. Anton J. Carlson, Chicago, delivered the annual Alpha Omega Alpha address to the University of Louisville School of Medicine, April 17, on "Observations on Science and Medicine in Russia and China."

**Society News.**—The committee on graduate courses in diseases of children of the Kentucky State Medical Association began a course at the Children's Free Hospital, Louisville, April 22, to continue each Wednesday for ten weeks. Interesting cases in the hospital are presented and newer methods of treatment discussed. Dr. Philip F. Barbour, Louisville, is in charge.—At the final meeting for the year of the Jefferson County Medical Society, Louisville, a discussion of the

management of epidemics was presented by Drs. Fred W. Caudill, who spoke on epidemic meningitis; Ben W. Smock, typhoid, and Samuel J. Brownstein, diphtheria. At the meeting, June 1, speakers were Drs. Karl D. Winter, on "Cautery Pneumonectomy for Lung Abscess"; Rettig A. Griswold and Edward M. Drissen, "Stab Wounds of the Heart"; Armand E. Cohen and Maurice G. Buckles, "Modern Treatment of Bronchial Asthma."—Dr. Roy Glenwood Spurling, Louisville, addressed the Louisville Surgical Society, June 5, on "Spinal Cord Tumors."

### MASSACHUSETTS

**Personal.**—Dr. John A. Foley has been named clinical professor of medicine at Boston University School of Medicine and Dr. William Reid Morrison, clinical professor of surgery.

**Milk Company Indicted.**—The *New England Journal of Medicine* reports that the chief officials of the Whiting Milk Companies have been indicted by a Suffolk grand jury for distributing in large quantities, as fresh cow's milk, a grossly adulterated substance. During the milk shortage of the March floods, according to the contention of the Boston Health Department, the Whiting Milk Companies conspired to manufacture a product from an inferior grade of Dutch skimmed milk powder and rancid South American butter; over 100,000 quarts was sold to chain stores in the poorer districts of Boston as pure milk. The journal points out that the Whiting Milk Companies were convicted in 1932 of adding a foreign substance to milk and paid a fine.

**Dr. Russell Awarded Medal.**—Dr. Frederick F. Russell, lecturer in preventive medicine and hygiene and epidemiology, Harvard Medical School, Boston, and formerly director of the International Health Division of the Rockefeller Foundation, has been awarded the Public Welfare Medal of the National Academy of Sciences. Dr. Russell retired Sept. 1, 1935, as director of the International Health Division. From 1920 to 1923 he was director of the public health laboratory service of the International Health Board. From 1923 until his resignation in 1935 he was general director of the board. The Public Welfare Medal is provided through the Marcellus Hartley Fund, a trust established in 1913-1914 through a gift from Mrs. Helen Hartley Jenkins in memory of her father, Marcellus Hartley.

### MINNESOTA

**Lectureship in Honor of Dr. Lyon.**—The establishment of the Elias Potter Lyon Medical Lectureship at the University of Minnesota has been announced as a tribute to Dr. Lyon, dean of the medical school, who is retiring from active service at the close of the present academic year. The fund for this purpose is to be raised through subscriptions by alumni, faculty, students and friends. Contributions should be sent to Mr. William T. Middlebrook, comptroller, University of Minnesota, Minneapolis.

**Society News.**—At a meeting of the Minnesota Academy of Ophthalmology and Otolaryngology in Rochester, May 5, speakers were Drs. Henry L. Williams Jr. on "Analysis of Cases of Petrositis"; Gordon B. New, "Benign Tumors of the Larynx"; William L. Benedict, "Tumors of the Orbit"; Hugo L. Blair, "Physiologic Factors in Perimetry," and Philip S. Hench, "Fever Therapy." All are of Rochester.—Dr. Robert G. Green, Minneapolis, discussed "Epizootiology of Tularemia" before the Minnesota Academy of Medicine, May 13.

**Personal.**—Dr. William J. Mayo, Rochester, delivered the commencement address at Notre Dame University, South Bend, Ind., June 7; both William J. and Charles H. Mayo received honorary degrees on this occasion.—Dr. John A. Malmstrom has resigned as health officer of Virginia to return to private practice.—Dr. Pierre C. Pilon, Paynesville, was guest of honor at a dinner recently, given in recognition of his completion of fifty years in the practice of medicine.—Dr. Anthony J. Spang has been appointed medical superintendent of the St. Louis County Hospital at Buhl, succeeding Dr. Oliver E. Sarff.

### MISSISSIPPI

**List of Automobile Victims.**—The state board of health has published a pamphlet dramatizing deaths from automobile accidents, attributing them not to "accidents" but to specific causes. The pamphlet points out that recklessness, carelessness, foolishness and drunkenness are the causes. In addition to statistics, it lists the names, classified according to counties, of persons who died in Mississippi in 1935 in automobile accidents or as the result of automobile accidents. Motor vehicle deaths in Mississippi have increased 83 per cent in the past four years.

## NEBRASKA

**Personal.**—Dr. Clarence S. Moran has recently been promoted to be assistant professor of pathology at Creighton University School of Medicine, Omaha, and Dr. William Howard Schmitz, associate professor of urology.—Dr. Inez C. Philbrick, Lincoln, has resigned after many years as resident physician for women at the University of Nebraska.—Dr. Archibald R. McIntyre, professor of physiology and pharmacology at the University of Nebraska College of Medicine, Omaha, has been appointed chairman of the department.

## NEW MEXICO

**Bureau of Child Welfare.**—In a news item published in *THE JOURNAL*, May 2, under the heading "Child Welfare Extended with Federal Funds," the state bureau of child welfare was mentioned as a division of the state department of public health. The bureau of child welfare and the bureau of public health are independent bureaus.

## NEW YORK

**Personal.**—Dr. Lawrason Brown, Saranac Lake, received the honorary degree of doctor of science at the annual commencement of the Medical College of Virginia, Richmond, June 2.—Dr. Jacob E. K. Morris, Olean, was honored with a banquet given by his colleagues and other friends recently to celebrate his golden anniversary in the practice of medicine.

**Annual Public Health Conference.**—The annual conference of health officers and public health nurses will be held at the Grand Union Hotel at Saratoga Springs, June 23-25. Among physicians on the program are:

- Dr. Floyd S. Winslow, Rochester, president of the Medical Society of the State of New York, Specialization in Public Health.
- Dr. Rufus I. Cole, New York, Pneumonia Control.
- Dr. Warren T. Vaughan, Richmond, Va., Hay Fever Pollen Reactions—To What Extent Are They Preventable?
- Dr. Paul A. O'Leary, Rochester, Minn., What the Treatment of Syphilis Accomplishes.

One session will be devoted to a symposium on tuberculosis with the following speakers: Drs. Max Pinner, Oneonta; James Burns Amberson Jr., New York, and Ethan Flagg Butler, Ithaca, and Mrs. Violet Hodgson, R.N., supervisor of tuberculosis outpatient nursing, state department of health.

## New York City

**Society News.**—The Public Health Association of New York City was organized May 18, made up of New York members of the American Public Health Association.—The Medical Society of the County of Queens held a joint meeting with the Queens County Bar Association, May 26, with the following speakers: Mr. Lloyd P. Stryker, formerly counsel to the Medical Society of the State of New York, on "The Doctor, the Law and the State"; Alexander O. Gettler, Ph.D., professor of toxicology, New York University College of Medicine, "The Role of Toxicology in the Medicolegal Autopsy"; Charles P. Sullivan, district attorney, Queens County, "Crime Among Juveniles," and Dr. Jacob Werne, assistant county medical examiner, "Autopsy Experiences in the Evaluation of Trauma."—Speakers at a meeting of the New York chapter of the Pan American Medical Association, May 27, were Drs. William Wayne Babcock, Philadelphia, on "Diagnosis and Treatment of Malignancy of the Intestinal Tract"; Frederick M. Allen, "Management of Diabetic Patients Requiring Abdominal Surgery," and William A. Kellogg, "Vesico-Intestinal Fistula."—Drs. Irving Sherwood Wright and Allen O. Whipple addressed the Medical Society of the County of Kings, May 19, on "Present Status of Peripheral Vascular Disease: Diagnosis and Treatment" and "Studies in the Combined Clinic on Splenic Disease" respectively.—Dr. John F. Erdmann addressed the New York Surgical Society, May 13, on "Tumors of the Uterus, with Special Reference to Fibroids."

## NORTH CAROLINA

**Society News.**—Dr. James W. Tankersley, Greensboro, was elected president of the North Carolina Academy of Surgery at the annual meeting in Asheville recently.—At the quarterly meeting of the Fourth District Medical Society in Goldsboro, April 28, speakers were Drs. Paul V. Anderson, Richmond, Va., on "Facts and Fallacies Concerning Insanity"; Henry B. Ivey and Corbett E. Howard, Goldsboro, on "X-Ray Study of Breast Lesions," and Richard S. Anderson, Rocky Mount, "Carcinoma of the Jejunum."—Dr. Tibor de Cholnoky, New York, addressed the Buncombe County Medical Society, Asheville,

April 20, on "Cancer and Electrosurgery."—Dr. Leroy J. Butler, Winston-Salem, was elected president of the North Carolina Pediatric Society at the annual meeting in Asheville, May 6.

## NORTH DAKOTA

**State Medical Election.**—Dr. Edwin L. Goss, Carrington, was chosen president-elect of the North Dakota Medical Association at the annual meeting in Jamestown in May, and Dr. William A. Gerrish, Jamestown, was installed as president. Drs. William H. Long, Fargo, and Lee B. Greene, Edgeley, were elected vice presidents and Dr. Albert W. Skelsey, Fargo, was reelected secretary. The 1937 meeting will be held in Grand Forks.

## OHIO

**"Alumni Day Clinics" at Cincinnati.**—Alumni of the University of Cincinnati College of Medicine were guests of the college for a program of clinics at the Cincinnati General Hospital, June 4. In charge of the clinics were Drs. Mont R. Reid, Burr Noland Carter, Marion A. Blankenhorn, Julien E. Benjamin, Robert R. MacDonald and Glenn E. Cullen, Ph.D. The afternoon was devoted to visits to the university's research laboratories. The annual alumni banquet was held at the Netherland-Plaza Hotel.

**Personal.**—Dr. John L. Jones, Medina, health commissioner of Medina County, has been appointed special investigator in the bureau of child hygiene of the state department of health. He will make a detailed investigation of maternal deaths in cooperation with the Hospital Obstetric Society of Ohio, it is reported.—Dr. Tom Douglas Spies has been promoted from assistant to associate professor of medicine at the University of Cincinnati College of Medicine and Dr. Eugene B. Ferris Jr., from instructor to assistant professor of medicine.

**Sectional Meeting.**—The Northwestern Ohio Medical Association held its ninety-second annual meeting at Findlay, June 2. After a golf tournament at the Findlay Country Club, the following program was presented:

- Dr. Thomas K. Brown, St. Louis, Puerperal Infections.
- Dr. John T. Murphy, Toledo, Use of X-Rays in the Treatment of Cancer of the Breast.
- Dr. John A. Toomey, Cleveland, A Critical Evaluation of Recent Advances in Contagious Diseases.
- Dr. Fred W. Rankin, Lexington, Ky., Modern Treatment of Cancer of the Lower Gastro-Intestinal Tract.
- Dr. Roy W. Scott, Cleveland, Diagnosis and Management of Patients with Cardiovascular Disease.
- Dr. Stanley R. Woodruff, Jersey City, N. J., Modern Methods of Combating Urinary Infections.

Dr. Amos O. Squire, Ossining, N. Y., former chief physician at Sing Sing Prison, gave an address at the dinner in the evening at the Elks' Club.

## PENNSYLVANIA

**Personal.**—Dr. Lewis C. Rowles, Clearfield, has been appointed medical director of Clearfield County to succeed Dr. Horatio L. Woodside, Bigler, who resigned in October 1935.—Dr. Albert M. Sittler, Bowmanstown, celebrated in April the fiftieth anniversary of his graduation from Jefferson Medical College, Philadelphia.—Dr. Arthur P. Noyes, Howard, R. I., has been appointed superintendent of the Norristown State Hospital, succeeding Dr. Annie R. Elliott.

**Graduate Assembly in Harrisburg.**—The Harrisburg Academy of Medicine presented its third graduate medical assembly at the Penn-Harris Hotel, May 7. Speakers were:

- Dr. Thomas Fitz-Hugh Jr., Philadelphia, Management of Certain Blood System Diseases.
- Dr. William F. Rienhoff Jr., Baltimore, Carcinoma of the Lung.
- Dr. Samuel A. Levine, Boston, Bedside Recognition and Treatment of Cardiac Irregularities.
- Dr. Joseph F. McCarthy, New York, Interrelation of Urology with General Medicine.
- Dr. Alan G. Brown, Toronto, Common Errors in Diagnosis and Treatment in Diseases of Children.
- Dr. Chevalier Jackson, Philadelphia, Diseases of the Larynx—Benign and Malignant.

## Philadelphia

**Meeting of Undergraduate Association.**—The twenty-eighth annual meeting of the Undergraduate Medical Association of the University of Pennsylvania School of Medicine was held May 7. Fourteen students presented papers. Addresses were made by the following guests: Drs. George R. Minot, Boston, on "Anemia and Its Relation to the Gastro-Intestinal Tract"; Derek Denny-Brown, neurologist to St. Bartholomew's Hospital, London, "Innervation of the Bladder and Vesical Sphincters" and Carl F. Schmidt, "Intrinsic Control of Cerebral Circulation."

**Dr. Burr Honored.**—Friends of Dr. Charles W. Burr gave him a testimonial dinner, April 25, at the Union League on the occasion of the fiftieth anniversary of his graduation in medicine and his election to the presidency of the Medical Alumni Society of the University of Pennsylvania. Dr. Daniel J. McCarthy was toastmaster. Eight classmates of Dr. Burr attended the dinner, as follows: Drs. John F. Culp, Harrisburg; Elliston J. Morris, William E. Parke, Charles J. Homan, Otto A. Rath, Paul J. Sartain, William H. Teller and William Zentmayer, all of Philadelphia.

**Antinnoise Ordinance Adopted.**—The city council of Philadelphia has adopted a noise abatement ordinance prepared by a special committee of the Philadelphia County Medical Society. The new ordinance prohibits sounding of automobile horns "except when reasonably necessary for the prevention of accidents," building operations at night except by special permit, the use of sound devices by peddlers, "unnecessary noise" in handling trash, ash and garbage cans, and the use of gongs, sirens or exhaust whistles on any vehicles except those of the police and fire bureaus, public utilities and hospitals. Loud playing of radios in homes or in front of stores is also among the specific noises forbidden in the ordinance. Penalty for the first offense is a \$10 fine, for the second \$25 and for the third \$50. Prison sentence may be imposed for failure to pay the fine.

### SOUTH DAKOTA

**State Medical Election.**—Dr. Earle A. Pittenger, Aberdeen, was chosen president-elect of the South Dakota State Medical Association at the annual meeting at Sioux Falls, May 4-8, held as a part of the Inter-Allied Professional Association. Dr. James L. Stewart, Nemo, was installed as president and Dr. John F. D. Cook, Langford, was elected vice president. Dr. Cook will continue to serve as secretary for another year to fill out his term. Next year's meeting will be in Rapid City. Dr. Burt A. Dyar, Pierre, was elected executive secretary for the interallied council.

### TENNESSEE

**Society News.**—Dr. Ralph O. Rychener, Memphis, was elected president of the Tennessee Academy of Ophthalmology and Otolaryngology at the annual meeting in Memphis, April 13. Dr. John M. Lee, Nashville, was made president of the Tennessee Pediatric Society, which met April 14.—At the meeting of the Dyer, Lake and Crockett Counties Medical Society, May 6, speakers were Drs. David H. James and Joseph H. Francis, Memphis, on medical and surgical aspects, respectively, of megacolon; Jesse Paul Baird, Dyersburg, clinical types of ascites, and Ernest G. Kelly, Memphis, intestinal obstruction.—Dr. Marvin M. Cullom, Nashville, addressed the Davidson County Medical Society, Nashville, May 5, on "Chronicity of Sinus Disease: Its Relation to Middle Ear Infections, Deafness and Constitutional Diseases."—Dr. Russell B. Howard, Clinton, addressed the Campbell County Medical Society, Jellico, April 30, on modern therapy of syphilis.—The Chattanooga and Hamilton County Medical Society met at Pine Breeze Sanatorium, May 7, with Drs. John Alexander Stewart, Eugene A. Gilbert and James L. Hamilton speaking on various phases of tuberculosis.—Dr. Leroy E. Coolidge, Greeneville, addressed the Greene County Medical Association, May 5, on diagnosis and treatment of goiter.

### TEXAS

**Incubator Babies at Exposition.**—A hospital for incubator babies is a feature of the Texas Centennial Exposition, Dallas, which opened June 6. The hospital is sponsored by the Woman's Auxiliary of the Bradford Memorial Hospital and Dallas Pediatric Society. The society invites all physicians to make their headquarters in this exhibit, where a special reception room has been arranged. The physician's personal card at the door will admit him, it is announced.

### VIRGINIA

**Hospital Meeting.**—The Tri-State Hospital Association, composed of the state associations of the Carolinas and Virginia, held its annual meeting at Old Point Comfort in April. Dr. Lewis E. Jarrett, Richmond, was reelected president of the Virginia association and Dr. Moir S. Martin, Mount Airy, was elected president of the North Carolina association. South Carolina will name its officers later.

**Society News.**—Speakers at a meeting of the Fauquier County Medical Society, Warrenton, April 30, included Drs. John A. Gibson, Leesburg, on "Doctors in Court and How

They Should Testify" and William O. Bailey, Leesburg, "Practice of Medicine in Modern Russia."—Dr. Edwin W. Burton, University, was elected president of the Virginia Academy of Otolaryngology and Ophthalmology, May 2, at the annual meeting in Richmond. Guest speakers were Drs. Alfred Cowan and Chevalier L. Jackson, Philadelphia.—Meningitis was the subject for discussion at the annual meeting of the Clinch Valley Medical Society in Norton, April 25, at which Dr. Sara E. Branham of the National Institute of Health, Washington, D. C., was the guest speaker.

### WASHINGTON

**Graduate Lectures.**—The twentieth annual course of medical lectures and clinics will be presented by the University of Washington, July 20-24, in Seattle. Lecturers will be:

Dr. Harvey B. Stone, associate professor of surgery, Johns Hopkins University School of Medicine, Baltimore.

Dr. James H. Means, Jackson professor of clinical medicine, Harvard Medical School, Boston.

Dr. Wilburn Smith, professor of gynecology, College of Medical Evangelists, Los Angeles.

Dr. Lewis John Pollock, professor of nervous and mental diseases, Northwestern University Medical School, Chicago.

The fee for the course, including the annual banquet, will be \$10. Each evening there will be a "no-host" dinner, followed by a lecture. A trip to Mount Rainier will conclude the session. Further information may be obtained from the University Extension Division, University of Washington, Seattle.

### WEST VIRGINIA

**Society News.**—Dr. Hugh G. Beatty, Columbus, Ohio, addressed the Cabell County Medical Society, Huntington, May 14, on "Harelip and Cleft Palate."—At a meeting of the Kanawha County Medical Society in Charleston, May 12, speakers were Drs. Archibald P. Hudgins and Howard W. Angell, on "The Sterile Couple" and "Orbital Abscess" respectively.—Dr. Austin I. Dodson, Richmond, addressed the Harrison County Medical Society, Clarksburg, May 7, on "Relations of Focal Infections to Diseases of the Urinary Tract."—Drs. Wade H. St. Clair and Dean L. Hosmer, Bluefield, addressed the McDowell County Medical Society, Welch, May 13, on "Intraperitoneal Emergencies" and "Tumors of Bone" respectively.—Speakers at a meeting of the Raleigh County Medical Society in Beckley, May 21, were Dr. Isidore I. Hirschman, Huntington, on "Peripheral Arterial Disease" and Mr. Clarence Meadows, Beckley attorney, on "The Doctor on the Witness Stand."—Dr. Max M. Peet, Ann Arbor, Mich., addressed the Ohio County Medical Society, Wheeling, May 1, on surgery of the sympathetic system.

### WISCONSIN

**Illegal Practitioner to Leave State.**—L. A. Carpenter, who has been practicing medicine in Prairie du Sac, pleaded guilty recently to advertising himself falsely as a physician and to treating the sick without a basic science certificate. He was released on his promise to leave Wisconsin and to remove his advertising from newspapers, farm magazines and telephone directories at once.

**Graduate Courses.**—Two courses of graduate lectures in obstetrics and pediatrics were begun May 18 under the auspices of the state board of health at the suggestion of the State Medical Society of Wisconsin. Social security funds are defraying the expenses. Instructors are members of the faculties of the University of Wisconsin School of Medicine, Madison, and Marquette University School of Medicine, Milwaukee. Towns in which the lectures will be given for six weeks are Manitowoc, Appleton, Waupaca, Oshkosh, Tomah, La Crosse, Whitehall, Marshfield and Stevens Point. It is expected that other courses will be planned as funds become available.

**Society News.**—A symposium on cancer was presented at a meeting of the Dane County Medical Society in April at Madison; speakers were Drs. James P. Dean, Samuel B. Pessin, Ernest A. Pohle, all of Madison, and Cleveland J. White, Chicago.—Dr. Elmer L. Sevringhaus, Madison, spoke on "Endocrine Aspects of Menstrual Disturbances" at a meeting of the Outagamie County Medical Society at Appleton, April 21.—Dr. Roy D. McClure, Detroit, addressed the Medical Society of Milwaukee County, May 8, on "Artificial Fever Therapy." The Milwaukee Professional Men's Orchestra under the direction of Dr. Robert O. Brunkhorst gave a concert at this meeting.—Dr. Gilbert J. Rich addressed the Milwaukee Neuropsychiatric Society, April 23, on "Recreational Treatment of Prepsychotics."

## GENERAL

**Sight Conservation Classes.**—The National Society for the Prevention of Blindness announces that special courses for teachers and supervisors of sight-saving classes will be offered at the summer sessions of the following schools: University of Cincinnati, University of California at Los Angeles, State Normal School at Oswego, N. Y., and Teachers College, Columbia University, New York. Details may be obtained from the university or college.

**Results of Obstetric Examinations.**—Fifty-nine applicants were approved for certification by the American Board of Obstetrics and Gynecology in the examinations held in Kansas City during the annual session of the American Medical Association. Twenty-two were conditioned or failed. The next written examination and review of case histories of group B applicants will be held in various cities of the United States and Canada November 7. Application blanks and booklets of information may be obtained from Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh. Applications should be filed with the secretary sixty days prior to the scheduled date of examination.

**Survey of Teaching of Preventive Medicine.**—Dr. John G. Fitzgerald, dean of the faculty of medicine and director of the school of hygiene and of Connaught Laboratories, University of Toronto, is to make a survey of methods of teaching preventive medicine sponsored by the Rockefeller Foundation. Dr. Fitzgerald, assisted by Dr. Charles Edward Smith of Stanford University School of Medicine, San Francisco, will visit medical schools in the United States, Canada, the British Isles and European countries in the course of the studies. Dr. Fitzgerald will resign as dean at Toronto June 30 and will spend a year on the survey beginning September 15. It is expected that he will return in September 1937 as director of the school of hygiene and of Connaught Laboratories.

**Medical Bills in Congress.**—*Changes in Status:* S. 4627 has passed the Senate, proposing to create a Division of Stream Pollution Control in the Bureau of the Public Health Service. The Revenue Act of 1936, H. R. 12395, has passed the Senate, with amendments. An amendment was adopted by the Senate proposing to amend the Harrison Narcotic Act to provide that a person not registered as an importer, manufacturer, producer or compounder, and lawfully entitled to obtain and use narcotic drugs in a laboratory for the purpose of research, instruction or analysis, shall pay a special tax of \$1 per annum, and shall keep such special records as the Commissioner of Narcotics, with the approval of the Secretary of the Treasury, may by regulation require.

**Seminar on Physical Therapy.**—The fourth annual seminar of the Western section of the American Congress of Physical Therapy will be held in Los Angeles, June 18. Dr. William Bierman, New York, as guest speaker, will discuss, among other subjects, "Clinical Use of Short Wave Currents." Speakers will include:

Dr. Julius R. Scholtz, Los Angeles, Use of Ultraviolet Radiation in Clinical Medicine, with Special Reference to Cutaneous Diseases.  
Dr. Henry Borsook, Pasadena, Vitamins in Medicine.  
Dr. William Rains, Los Angeles, attorney for Medical Protective Company, Legal Aspects of Physical Therapy.

Dr. Edward M. Pallette, Los Angeles, president of the California Medical Association, will be toastmaster at the annual banquet in the evening, and Dr. Bierman will discuss "Fever Therapy."

**Society News.**—Dr. Benjamin O. Whitten, Clinton, S. C., was chosen president of the American Association on Mental Deficiency at its annual meeting, May 4; Dr. Harry C. Storrs, Wassauc, N. Y., vice president, and Dr. E. Arthur Whitney, Elwyn, Pa., secretary. The next annual meeting will be held in Atlantic City in May 1937. —Dr. Haven Emerson was reelected chairman of the National Committee on Maternal Health, Inc., at its annual meeting in New York, April 24; Dr. Robert L. Dickinson was named chairman of the executive committee; Dr. Frederick C. Holden, medical director and treasurer, and Dr. Howard C. Taylor Jr., vice chairman and secretary. —Dr. William S. Tillet, Baltimore, was elected president of the American Society for Clinical Investigation at the annual meeting in Atlantic City, May 4. Dr. Luther Emmett Holt Jr., Baltimore, was made vice president and Dr. Joseph M. Hayman Jr., Cleveland, secretary. —Dr. Chester M. Jones, Boston, was elected president of the American Gastro-Enterological Association at the annual meeting in Atlantic City, May 4. Drs. Ralph C. Brown, Chicago, and Ernest H. Gaither, Baltimore, were made vice presidents. —The National Medical Association will hold its annual meeting in Philadelphia, August 16-22.

## LATIN AMERICA

**National Tuberculosis Council.**—Announcement is made of the creation of a National Tuberculosis Council to direct antituberculosis work and the care of tuberculosis patients in Cuba. Decree law number 706, under which the council is established, provides that it will have charge of hospitals, visiting nurses and other phases of tuberculosis prevention work. A certain percentage of the proceeds from the weekly drawings of the national lottery will be placed at the disposal of the council for this work. In addition, donations legally made to this fund will be used to defray expenses. Initial funds to be collected will be used to construct a sanatorium in the Trinidad mountain section of the province of Santa Clara.

## FOREIGN

**Personal.**—Sir Robert Muir will retire, September 30, from the chair of pathology at the University of Glasgow, according to *Science*. He has held this position since 1900. The retirement is also announced of Dr. Thomas K. Monro, who has held the chair of the practice of medicine since 1913.

**Congress on Malaria.**—The third International Congress on Malaria will be held in Madrid, October 12-16, under the presidency of Prof. Gustavo Pittaluga, Madrid. The secretary asks that copies of all reports and communications, with brief summaries for the press (not more than twenty lines), be sent before July 1. Applications for membership must be accompanied by two small photographs to be used in the members' personal cards, which will be essential for all matters concerning the congress as well as for reductions in transportation costs obtained by the committee on arrangements. Dr. Emilio Luengo, chief of the parasitology service at the National Institute of Health, Madrid, is secretary general of the organizing committee of the congress. Correspondence should be addressed to him at Instituto Nacional de Sanidad, Calle de Recoletos 19, Madrid.

**International Conference on Tuberculosis.**—The tenth conference of the International Union Against Tuberculosis will be held in Lisbon, Portugal, September 7-10, under the chairmanship of Dr. Lopo de Carvalho, president of the union. The biologic subject to be discussed is "Radiological Aspects of the Pulmonary Hilum and Their Interpretation," in discussion of which the United States will be represented by Dr. Henry C. Sweany, Chicago; the clinical subject, "Primary Tuberculous Infection in the Adolescent and the Adult," with Dr. Robert E. Plunkett, New York State Department of Health, Albany; and the social subject, "The Open Case of Tuberculosis in Relation to Family and Associates," with Dr. Charles J. Hatfield, Philadelphia, as a discussor. Application for membership and other information concerning trips to the conference may be obtained from the National Tuberculosis Association, 50 West Fiftieth Street, New York City.

## Government Services

## Forty States Free from Bovine Tuberculosis

Nebraska is the fortieth state to be certified as a modified accredited area in the campaign to eradicate bovine tuberculosis, the U. S. Department of Agriculture announces. Most of the tuberculin testing has been done within the past two years. It will now be necessary only to retest the various counties at regular intervals as a precaution to keep the disease from gaining another foothold.

## Hospitals for Indians

Appropriations from the Public Works Administration have been set aside for hospital construction on the Blackfeet and Crow reservations in Montana, the Sisseton, Yankton and Crow Creek reservations in South Dakota, the Cherokee reservation in North Carolina, and at Cass Lake, Minn., for the Chippewa Indians, the Department of the Interior announces. The Indian Service now has under construction hospitals for the Zuni Indians in New Mexico, the Warm Springs group in Oregon, the Western Shoshone tribe in Nevada, and another at Yuma, Ariz. An Indian unit at Ah-Gwah-Ching, Minn., and a thirty-eight bed hospital on the Colville reservation, Washington, have recently been completed. The total amount made available for all these projects is \$1,870,026. It is planned that about 1,000 beds will have been added to the facilities for Indians when the present and contemplated construction is finished.

#### The Need for Physical Education

About eighteen months ago the minister of health suggested to the council of the British Medical Association that something might be done to bring home to the public the benefits of physical culture. The result was that the council appointed a physical education committee consisting largely of physicians and others interested in physical culture. The committee has presented an elaborate report in which it makes the startling statement: "Not less than 40 per cent of the population between the ages of 14 and 40 need, but do not participate adequately, if at all, in physical recreation or training. The results are only too evident in the defective physique of large sections of the population." To raise the national standard, it is recommended that the following measures be taken at once: (1) extended provision by local authorities of facilities of all kinds for physical recreation, especially for outdoor games and swimming; (2) greater financial assistance to the physical activities of voluntary organizations; (3) closer cooperation between all agencies, whether official or voluntary, concerned with physical recreation; (4) propaganda, including the use of the cinema; (5) increased supply of qualified teachers; (6) more intimate relation between physical education and the science and part of medicine. It is pointed out that three government departments—the Ministry of Health, the Ministry of Labor and the Board of Education—are concerned with physical education. Immediate steps should be taken on a national scale for coordinated action, which might be administered by the recently formed Central Council of Recreative Physical Training. As to the relation between physical education and medicine, the report states: "Physical education has progressed from being a narrow specialty of the gynosium and games field, in the hands of instructors with limited training and apprehension, toward a national service, which aims at securing greater health, fitness and happiness for the people as a whole, irrespective of age or sex. It should take its place among the great social services as a branch of public health." Organizers of physical education should be appointed by all local authorities.

#### PHYSICAL EDUCATION IN SCHOOLS

Physical education in schools should include systematic gymnastic exercises, games and other activities, each playing its part in a balanced scheme of training. Gymnastic training should not be regarded as subsidiary to field games and athletic sports. Swimming should be taught as a regular part of physical education in all schools. Instruction in elementary physiology and personal hygiene as a branch of general science should be regarded as an essential part of physical education. These subjects should be taught in a practical way and should be related both to the gymnastic training and to the periodic medical examination. Local education authorities should provide suitable clothing and gymnastic shoes for children whose parents cannot do so.

#### THE MEDICAL SUPERVISION OF PHYSICAL EDUCATION

Physicians have hitherto been concerned chiefly with the physical treatment of the abnormal rather than the normal, and with the individual rather than the community. They have devoted attention to the cure and prevention of disease rather than the perfecting of the race. Nevertheless physicians engaged in attending communities such as industrial organizations, schools and the defense services have long been pressing the need for

extending physical education to the whole population. The physician, too long absorbed in the treatment of individuals, is more and more coming to realize that he has an important part to play in furthering communal well being. The committee considers that not only should there be regular medical examinations in schools but in all matters concerning physical development and health of the individual pupil there should be close cooperation between the head master, the school doctor, the parents and the teacher of gymnastics. This is especially desirable in the prevention of strain, which girls are liable to suffer in mixed schools. Medical supervision should be available to ensure that unfit children do not participate in unsuitable or excessive exercises. Physicians should cooperate with teachers of gymnastics in investigating the physiologic requirements and effects of the various exercises with a view to the scientific arrangement of the syllabus of training. Postgraduate courses should be established to provide physicians with the special training which the medical supervision of physical education requires.

#### PHYSICAL EDUCATION FOR THOSE NO LONGER ATTENDING SCHOOL

To be of permanent value, physical education should be continued under expert guidance after the individual has left school. A considerable number of young people receive physical education at evening classes organized or financially assisted by the local authorities. But there is a deficiency of suitably trained leaders, and facilities for joining the classes are insufficient.

#### ALCOHOL AND TOBACCO CONDEMNED

The committee declares that alcoholic beverages are not necessary in physical training and may be harmful. Smoking, especially when practiced to excess and when the smoke is inhaled, is definitely injurious. Prolonged investigation has proved that excessive smoking (twenty cigarettes a day) is detrimental to endurance by making the heart irritable, with consequent earlier onset of fatigue.

#### Features of Malignancy

At the Royal College of Surgeons, Sir Robert Muir, F.R.S., professor of pathology at the University of Glasgow, delivered the Lister Memorial Lecture on "Malignancy, with Illustrations from the Pathology of the Mamma." He gave a survey of our knowledge of malignancy. He said that experimental work on transplantation of tumors showed that the margin between growth and nongrowth was comparatively narrow, and that there were numerous human cases of malignant cells being overcome and disappearing. Once acquired, malignancy seemed to be a permanent property of the cells; they might be destroyed or die out but not regain normal behavior. Research had advanced our knowledge of the etiology, but the nearest approach to a general statement which could be made was that the acquisition of malignancy was related to previous non-neoplastic proliferation. Three conditions might lead to this: 1. Chronic irritation in its widest sense. Nothing might be known of the nature of the irritant, as is carcinoma of the cervix. 2. Compensatory hyperplasia, such as occurred in the liver after loss of its substance. 3. Hormones.

The two main theories as to the cause of malignancy were that it was the result of a change in the mechanism of the cell and that it was produced by a virus. The change in the cell appeared to be twofold: an escape from the normal growth-controlling agencies of the body and the appearance of special structural characters. The parasitic theory of cancer had passed through many phases. It was generally recognized that if a parasite was concerned it must be an invisible microbe, such as a virus. But there was no evidence that malignancy was produced by a virus or viruses entering the body from outside, and experimental facts appeared to exclude this. Growths could be set up by carcinogenic agents so regularly,

not only when applied externally but also when introduced into the tissues, that access of a virus from outside on each occasion seemed impossible. The conclusion appeared inevitable that the virus must be present within normal tissues and act only when proliferation had been set by carcinogenic agents or in some other way.

#### MALIGNANCY IN THE BREAST

Recent research showed that a variety of structural changes in the mammary epithelium led up to malignancy. They consisted of (1) increased and altered secretion, accompanied by changes in type of epithelium and desquamation, and (2) hyperplastic proliferation of the epithelium. The hyperplasia was attended by coordinated increase of connective tissue. Thus there arose papillomatous growth in the ducts, often associated with cystic dilatation. The next stage was relative overgrowth of epithelium in comparison with stroma. This gradually passed on to proliferation of epithelium alone. Finally, the anaplasia became distinct; the cells and their nuclei varied in size, the latter becoming vesicular with distinct nucleoli. Ultimately masses, with all the characters of encephaloid carcinoma, appeared within the ducts. He believed that local intraduct carcinoma was quite common. The cells had acquired the characters of malignancy yet were still within normal bounds—a sort of tissue culture of malignant cells still within the test tube. Ultimately there was a break through the normal bounds, with ordinary infiltrating cancer as the result.

#### Avian Tuberculosis in Cattle

In a letter to the *Times*, F. C. Minnett, director of the Research Institute in Animal Pathology, Royal Veterinary College, contradicts the statement made by another correspondent that only recently has undeniable proof been obtained of the danger of cattle contracting tuberculosis from poultry. In the *Journal of Comparative Pathology and Therapeutics* in December 1932 he reported five cases of tuberculosis in cattle which were proved to be due to bacilli of the avian type. These cases occurred in three calves and two adult bovines belonging to three herds. In at least one of these herds there was evidence that other calves also were affected, while in two of the herds tuberculosis was proved by tuberculin testing or by postmortem examination to exist among the fowls, which had free access to the cattle. Minnett points out that tuberculosis of the avian type is not altogether rare in mammals. It has been encountered fairly extensively in pigs, and cases have been seen in wild animals kept in captivity and occasionally even in horses, deer and sheep. In mammals the disease is usually retrogressive and therefore not serious as far as the animal itself is concerned, but cattle so affected may react for a time to tuberculin. Although it is probable that infection is generally acquired in calfhood and is overcome by the time of adult life, two of the cases recorded by Minnett were in adults, one animal being 18 months old at the time of slaughter, while the other was an old cow. The knowledge now available shows the need for preventing poultry having access to cattle unless it is certain that tuberculosis is absent.

#### Trachoma in Palestine

The report for 1935 of the Ophthalmic Hospital of the Grand Priory in the British Realm of the Venerable Order of the Hospital of St. John of Jerusalem, whose chancery is in London, has just been published. The number of new patients seen during 1935 was 21,116. The incidence of trachoma among them reached the extraordinary height of 92 per cent, the highest recorded in the hospital. The warden of the order states that in the most backward villages of Palestine almost all the inhabitants beyond the age of infancy have trachoma. In the larger towns the incidence is much less, though there has been an increase in the wake of a cycle of severe epidemics of conjunctivitis.

#### Sodium Chloride Solutions for Postoperative Toxemia

The method of treatment termed rechloridation to combat postoperative complications has been the subject of a number of papers. Max Levy of Paris read one at the January 7 meeting of the Académie de médecine, citing some remarkable results from giving intravenously a 4 per cent solution of sodium chloride. There are many deaths following operation which are difficult to explain if the more common complications are excluded. Recent studies have revealed the existence of a postoperative toxemia which may not only be checked in its incipient stages but the development of which may be prevented by the administration of sodium chloride solution in high concentration. In its mildest form, such a toxemia presents itself in the first few days following operation as a feeling of exhaustion, slight evidences of intestinal paresis, decreased urinary output and lowered blood pressure. If the symptoms increase, the malaise and weakness become more marked, the tongue is dry, the blood pressure drops more, the pulse increases in rapidity, hiccup appears and the oliguria may progress to almost complete anuria.

The evolution of this more severe clinical picture varies greatly. The symptoms may recede spontaneously and slowly or a more serious termination may ensue either with a single symptom or with a combination of symptoms. Under the former heading one may encounter cases of (a) coma with anuria and Cheyne-Stokes respiration, (b) uncontrollable vomiting resembling an acute ileum, (c) marked irregular elevations of temperature or (d) a case in which the signs of cardiovascular disturbances predominate. A fatal outcome may ensue gradually or occur with lightning-like rapidity. As the result of the work of Chabanier and Lobo-O'Neill, Levy, Legueu and Fey and of Duval, the mechanism of such a postoperative toxemia has been greatly cleared up. The following working hypotheses, the majority of which have been proved by laboratory studies, have been set up:

1. Disturbance of nitrogenous metabolism.
2. Disturbance of chloride metabolism.
3. Lack of acid-base equilibrium.

The hypochloremia does not express itself by any important sign clinically. Following operation a patient may present a marked hypochloremia and yet seem to be making an uneventful recovery. On the other hand there may be only a slight hypochloremia and grave symptoms of toxemia may be present. This lack of concordance between certain laboratory evidence and clinical signs is true also of the variations of the blood urea. The increase in residual nitrogen seems to dominate the time of appearance and degree of severity of the symptoms of toxemia (postoperative).

In a postoperative case in which either the milder or more severe symptoms appear as previously mentioned, a chemical analysis of the blood and urine should be made immediately. The blood examination must include percentage of urea, plasma and globular chloride content and glycemia. The urine examination embraces percentage of urea, chlorides and acetone. All the results can be obtained within two hours. The marked decrease or complete disappearance of chlorides in the urine gives one the best idea of the degree to which chlorides have been withdrawn from the blood and tissues to be lodged in the operative zone. One should begin the treatment by the administration very slowly of 20 cc. of a 4 per cent solution of sodium chloride. The total amount of sodium chloride to be injected during the first and following days depends first on the degree of dechloridation. The more marked the diminution of chlorides in the urine, the more sodium chloride should

be given. Secondly, the patient whose symptoms of toxemia are very serious requires a larger amount of sodium chloride, i. e., more rechloridation, than a patient with only mild toxemia. Thirdly, the longer the symptoms have lasted, the more sodium chloride is needed. Twenty cc. is inadequate if all three of these are very marked. Under these circumstances the first dose should be from 30 to 40 cc. of the 4 per cent solution followed in from eight to twelve hours by a second one of 20 cc.

The blood and urine should be examined daily and the treatment continued until the blood chlorides and urea have returned to the normal figure, the quantity of urine is greatly increased, and all clinical symptoms have receded. In general, it suffices to give between 20 and 30 Gm. of sodium chloride the first day, between 10 and 20 the second day and between 5 and 10 the third.

The results of this rechloridation treatment have been most gratifying, especially following abdominal operations in general surgery and after prostatectomy.

#### Immediate versus Late Operation in Acute Osteomyelitis

A discussion took place at the March 4 meeting of the Académie de chirurgie as to whether the classic method of immediate operation in cases of acute osteomyelitis should be replaced by expectant treatment until a subperiosteal abscess has appeared. Leveuf advocated the latter method, basing his opinion on experience in sixteen cases. The shortest interval in which operation was performed was three days, the longest forty days. In fifteen of the sixteen patients only an abscess was drained. In one of the sixteen an operation (resection) was necessary in a case of acute osteomyelitis of the lower end of the radius with separation of the epiphysis. The presence of *Staphylococcus aureus* was demonstrated in all sixteen cases (children and adolescents). The best two methods of following the spontaneous evolution of an acute osteomyelitis are to observe the recession of the fever and the results of the blood cultures. The former reaches the normal level at about the fifteenth day in the average case after admission to the hospital. With the drop in temperature, an improvement in the general condition can be noted. This is especially striking in cases in which the onset has been accompanied by symptoms of severe toxemia.

The results of hemoculture are also a good criterion of the progress of the case. In cases of acute osteomyelitis which terminate in death and in which early operation has been of no avail the blood cultures remain positive throughout the period of clinical observation. In the sixteen cases in which operation was delayed, the hemoculture was negative in six. It was positive in the ten other cases on one or several occasions. The hemoculture remains positive from five to twenty-five days after admission to the hospital. At times the hemocultures that were positive become negative even when no operation has been performed. In others the hemocultures remain positive until after the abscess has been incised. In one case the hemocultures remained positive even after such an incision. In general, one can say that there is a certain relation between the severity of the osteomyelitis and the persistence of positive hemocultures. Radiography reveals bone changes at the end of fifteen days in the form of sequestrums, which serve as indications for operation; but these sequelae are minimal if one waits. Expectant treatment does not have a harmful influence on the bone lesions. This is especially true of osteomyelitis of the neck of the femur, as Ombredanne and Petit have already shown. Leveuf believes that early operations open bone and muscle areas where the defense against the toxins of *Staphylococcus aureus* has not yet been organized. The only danger of delayed operation is involvement of a joint adjacent to the osteomyelitic focus. Leveuf saw this in only one case. In such cases, early resection is indicated.

The discussion was opened by Bazy, who stated that the same principle of waiting until local defense has been established is true of peritonitis, empyema and infections involving soft tissues as well as in acute osteomyelitis. Sorrel believed that the teachings of Leveuf if carried out indiscriminately would lead to dangerous results. Mathieu also endorsed early operation, with the proviso that one should remove as little bony tissue as possible. The possible extension to an adjacent joint was also a reason why operation should not be delayed too long.

Grégoire said that he had opposed immediate operation ten years ago. He had been influenced in arriving at this opinion by the excellent results obtained by giving antistaphylococcus vaccines in cases of acute osteomyelitis. The only criticism to be made against the vaccine treatment is that it is too simple and hence a dangerous weapon in the hands of those who do not fully understand the pathology of acute osteomyelitis. A vaccine should not be used indiscriminately but only when there is a recrudescence of the fever.

#### Nature Medicine and "New German Medicine"

News of these movements have been reported from time to time in THE JOURNAL. It can almost be said that no fundamental difference exists between the two groups. The attempt has been made by the use of more forceful propaganda to penetrate the circle of those physicians who have been trained to think rationally and to practice accordingly. Numerous books on the subject are being printed. A few characteristic features of this literature will be mentioned. First of all, mention must be made of the "Biologic-Medical Pocket Manual" published by the director of the museum of hygiene at Dresden, Professor Martin, in collaboration with twenty-nine "physicians and scientists." This work is dedicated to that "New German Medicine" with which the national führer of medicine, Dr. Wagner, is closely identified and which he has done so much to further. "The New Medicine," says Dr. Wagner in a sort of introductory harangue with which the book begins, "cannot be founded on science in the strict sense of the term but rather on the National Socialist weltanschauung as it affects the fundamental nature and biologic laws of all happenings." The collaborating "scientists" have gone about their task with this idea in mind. The section of the book on nutrition rests principally on the teachings of the Zurich physician Dr. Bircher-Benner, who has made a German reputation through his courses and lectures within the reich. The physical methods are quite expertly worked out but they are carried far beyond their legitimate boundaries. Among other methods endorsed is that of treatment with multiple irritant punctures, although the use of this procedure in earlier times forms one of the darkest chapters in medical history. Artificially induced suppurations also are recommended. Treatment with medicaments shows the usual backward trend exemplified by the grossly exaggerated recommendations of vegetable preparations the efficacy of which remains to be demonstrated in actual practice. The book contains a pernicious advertisement section, a good example of how the unbelievable may actually come to pass. Here a language utterly different from that of standard medical literature is frequently encountered. Arsphenamine is not entirely dispensed with, although its use is expressly termed "provisional." This booklet of nearly 600 pages sells for the modest price of 3.50 reichsmarks and may be easily obtained by the medical profession as well as by the public (the distinction between physician and layman is no longer regarded as fundamental). The work would no doubt make amusing reading for the Council on Pharmacy and Chemistry.

Under present conditions, with these new doctrines receiving governmental sanction, it seems remarkable that a dissenting voice should be heard. Prof. F. O. Hess, hospital director in a city of medium size, has spoken his mind on the subject before the regional medical union. In the near future Nature Medicine and Biologic Medicine are to have a hearing in open convention, and one can scarcely wait until this comprehensive airing of the opposing points of view takes place. There exists today a danger of authentic factual data being shaken and upset by unproved assertions. As examples, Hess cites the widespread disuse of serotherapy, of vaccination against smallpox and the doubtful attitude toward all diagnostic methods. Physicians must reject those accounts of manifestly superior results which appear in popular publications together with a dig at scientific medicine. Such popular articles pass over in silence the accomplishments of regular medicine in the field of infectious diseases. Interesting sidelights are furnished by the discussion which followed this address. The Rudolph Hess Hospital of Dresden, which has dedicated itself to these Nature Cure methods, is now treating venereal diseases, notably gonorrhea and syphilis, exclusively with Nature Cure procedures. As the local dermatologic society has expressly stated, such treatment obviously is harmful to the patient and in addition fails to protect others, including future generations, from the infection.

The treatment of appendicitis, as described in a widely circulated "Handbook of Nature Medicine" by Brauchle, calls to mind the therapeutic methods of the year 1750, when medical science knew no better. A movement which advocates the use of poultices, fasting, purges and clysters in the treatment of appendicitis cannot be regarded as other than a decided backward trend of medical progress. The direction here taken by Nature Medicine imperils all the advances of proved worth in the treatment of the disease. From this noteworthy controversy physicians in other countries are able to form a good picture of the German situation.

In the same issue of the *Münchener medizinische Wochenschrift* that carries an account of these events, it is announced that the second International Congress on the Diagnosis of Iridal Disorders will be held at Nuremberg in May. Topics will be "Diagnosis of Iridal Conditions in Relation to General Diagnostic Methods" and "Diagnosis of Iridal Conditions in Digestive Disorders, with Especial Consideration of Differential Diagnosis." At the same time the national convention and centenary celebration will be held at Nuremberg, the center of the Nature Cure movement.

The sort of material it is possible to find in contemporary professional publications is exemplified by the following advertisement, which appeared in a widely circulating medical weekly toward the close of 1935: "Therapeutic Magnetizer with Complete Especially Strong Magnetizing Powers—Can Light Incandescent Bulbs of 220 Volts by Contact—Situation Wanted. Address . . ."

It will be interesting to see what the previously mentioned joint convention of "New German Medicine" and the "German Society of Internal Medicine" holds in store.

### German Women in the Professions

The number of active German academicians (university graduates with professional careers) is estimated at around 350,000. What proportion of this number are women can be determined from statistical reports of several professional groups. The National Medical Almanac, for example, and the statistics compiled by the League of German Women Physicians place the total number of women physicians in the German reich and Danzig as of 1935 at 3,675. This figure represents an increase of 8 per cent over 1932. Of these women 278 (7.6 per cent) are no longer professionally active. Those employed, that is, occupying regular posts, number 888 (24.2 per cent), an

increase over 1932. On the other hand, the percentage of women physicians in independent practice has decreased from 74 (in 1932) to 62.2. Of these 2,509 independent women practitioners the vast majority are in general practice; only 28.5 per cent are specialists. How strongly women feel drawn toward pediatrics is shown by the fact that 43 per cent (309) of the specializing women physicians are pediatricians. After pediatrics, other specialties engaged in by women follow at a considerable distance; thus, ninety-seven women gynecologists form 13.6 per cent of the total, seventy-four women ophthalmologists 10.4 per cent and sixty-six women internists 9.2 per cent. Geographic distribution of female physicians is remarkably uneven throughout the reich. Berlin contains 20 per cent of the professionally active women physicians, 518 in private practice, 153 occupying positions. In Berlin also is the largest proportion of women specialists, of whom forty-eight, nearly 36 per cent, are pediatricians; and yet whole provinces are without more than one or two women gynecologists each.

Of a total of about 52,000 German physicians, 7 per cent are women. The percentage of women admitted to the sick insurance practice is still smaller; of 31,146 insurance physicians, 1,224 (3.97 per cent) are women. Since the officially authorized national insurance societies numbered 6,250,000 females among their membership in 1933, it will be seen that the number of female physicians capable of treating female insurance patients is also quite small. Within the last few years 300 non-Aryan women physicians were excluded from the insurance practice on racial grounds, while in 115 other instances of license revocation the physicians were chiefly married women and the purpose was to eliminate the so-called state of double earning. In 1934, 348 women began the study of medicine, as against 889 in 1933 and 1,151 in 1932.

According to official statistics for 1933, of a total 12,120 dentists, 1,250 were women. Of these women dentists, 692 were independent and 558 employed. The proportion of males to females was the same as among the medical profession; the women formed 7 per cent of all practicing dentists. The decline in the number of female dental students has been even greater than the decline in the number of female medical students; in 1934 only sixty-two women began the study of dentistry, against 357 in 1932.

In 1933 the profession of veterinarian was followed by fifty-three women. Only a few of this group, namely, fifteen, were independent, the other thirty-eight being employed. While twenty women are students of veterinary medicine in the universities, only one woman began a course of study in this field in 1934.

According to official records there were 3,716 women pharmacists in 1933, including those undergoing training. A new report for 1934 lists 104 pharmacy proprietresses, 425 employed women pharmacists and 1,064 women pharmacy assistants—altogether 1,593 women in a total of 14,128 pharmacists of both sexes. There were besides in the same year 727 women pharmacy apprentices. Restriction of the number of pharmacies in which apprenticeships may be filled has caused a decline in the number of apprentices. More than 50 per cent of male pharmacists are independent proprietors, but not 7 per cent of the women reach this goal.

One of the most important academic professions with regard to women is that of "teacher in the higher schools." Among a total 37,505 teachers of this rank, including school heads, 5,428 women were listed.

While the number of female political economists is unknown, there were in 1933 thirty-six women judges and 251 women lawyers. In 1934, 104 women passed the second examination in jurisprudence. How small the future generation of women attorneys will be is illustrated by the fact that in 1934 only

seventeen women began the study of law. Figures for 1933 show 168 women among the evangelistic ministers and missionaries.

Compared with the total number of women in gainful occupations (around 11,500,000), women in the foregoing professions constitute a relatively small group. There were twenty-six women listed as lecturers on the university faculties for the winter semester 1935-1936. None of these women held full professorships, thirteen were unofficial extraordinary professors, and the remaining thirteen were instructors (*privatdozentinnen*, according to the previous designation). The twenty-six women members of the university faculties were distributed as follows: Berlin 6; Hamburg 5; Munich 4; Breslau, Giessen and Heidelberg, two each; one each at Göttingen, Düsseldorf (the Academy of Medicine), Jena, Marburg and Würzburg. The remaining German universities have no women faculty members: The following fields of specialization are represented by the twenty-six women lecturers: eight women profess as many medical specialties; namely (1) anatomy, (2) genetics, (3) ophthalmology, (4) hygiene and bacteriology, (5) dermatology and venereology, (6) pharmacology, (7) pathologic physiology and (8) dentistry. Fields other than medicine and the number of women professing therein are international law and jurisprudence one, political economy three, philology three, psychology and pedagogy three, natural sciences a total of eight of which four are in botany (which includes plant genetics), and one each in oceanography, zoology, chemistry and physics.

#### International Congress for Juvenile Protection

The International Congress for Juvenile Protection, which recently met at Brussels, held that attendance at establishments for children of preschool age should not be compulsory; furthermore, that governments should see that all such institutions possess (1) a teaching staff especially trained to deal with children of this age, (2) medical supervision that guarantees adequate puericulture (physical and moral upbringing of the children) and (3) a competent assisting personnel, the members of which while not exceeding their authority know how to facilitate the harmonious cooperation of the teachers, the physicians and the children's relatives. Additional recommendations of the conference were that the parents should be kept constantly informed as to the child's progress; that relatives, and mothers in particular, should be given as much beneficial instruction as possible, and that a record of the child's health should be maintained by cooperation on the part of the family and of the infant welfare organizations, the latter being subsequently replaced by other organizations with which the child of school age shall come in contact.

#### The Belgian Puericulture Centers

Under the auspices of the Belgian Puericulture Centers a model pediatric clinic has been built. The center for supervised familial placement will be temporarily housed at the clinic until the construction of its own new building on the outskirts of Brussels has been completed.

The puericulture clinic was formally opened in December 1933 by the queen, then duchess of Brabant. In it are hospitalized healthy children less than 6 years of age and children suffering from debility or noncontagious diseases who are unable to receive maternal care. When the mother is widowed or deserted the clinic takes in both mother and child. The children are isolated in tiny individual cubicles, which open on wide, covered balconies and which are separated one from the other by glass partitions. Each of the cubicles is equipped

with a special ventilating apparatus, a smooth radiator, easily washed, and a bath tub with hot and cold running water. Each child's necessities are kept in little individual glass wardrobes. Each upper story of the hospital building recedes from that directly below it and the width of these setbacks corresponds to that of the balconies. By this arrangement every floor of the building receives an equal amount of daylight.

The prescribed regimen for each little patient is prepared by the dietitians in a special diet kitchen. Direct communication is maintained between the diet kitchen and the pantries of each upper floor by means of an electrical dumbwaiter. By means of a pneumatic tube system, written dietary instructions can be transmitted without going astray. Sleeping apartments are especially designed for the care of prematurely born infants. This manner of housing the prematurely born has replaced the incubator, which obsolescent device is no longer used in modern pediatric institutions. The premature babies are cared for by a specially trained personnel which has charge of the constant feedings of breast milk. An operating room is equipped for minor surgical procedures. Children suspected of harboring contagious diseases are kept in the strictest isolation. Spacious reception rooms and consultation rooms are situated on the ground floor.

In addition to indigent children and children confided to its care by welfare organizations, the foundation accepts as patients the children of well-to-do parents. The income realized from the boarding of children of the latter class, small though it may be, enables the clinic to take better care of the less fortunate little ones. The institution is conducted on a strictly nonprofit basis.

Recently a school has been established in connection with the clinic which offers instructions in the theory and practical application of puericulture. Every student who passes the final examination receives a diploma in puericulture. The curriculum is designed for young girls possessing a general education and background at least of secondary school level, as well as for midwives and social workers who wish to complete their training in puericulture. The regular course covers a period of four semesters, but this is reduced to two semesters for social workers and to one semester for graduates in nursing and obstetrics. Students are required to reside at the clinic.

### SWITZERLAND

April 20, 1936.

#### The Organization of the Swiss Medical Profession

In Switzerland the foundation of the organized medical profession is the *Verbindung der Schweizer Aerzte* (League of Swiss Physicians), which, according to its constitution, draws its membership from the cantonal organizations affiliated with three linguistically differing groups: the *Verband deutschschweizerischer Aerztegesellschaften* (Federation of Medical Societies of Germanic Switzerland), the *Société médicale de la Suisse Romande* (Medical Society of French Switzerland) and the *Ordine dei medici del cantone Ticino* (League of Physicians of Ticino Canton [Italian Switzerland]). The *Verbindung der Schweizer Aerzte* is the ranking official organization of the Swiss medical profession. Among its aims may be mentioned investigation of scientific questions and promotion of advanced medical study, protection of professional interests by its power to make and to enforce suitable regulations in particular circumstances, and representation of the will of the Swiss medical profession in questions of public health and the control of disease. The *Verbindung's* legislative authority is vested in the *Schweizerische Aerztekammer* (chamber of Swiss physicians), which is composed of delegates from the several cantons. Each cantonal organization is entitled to elect one delegate and one alternate for each fifty members or fraction thereof. The term

of office is three years. The *aerztekammer* holds a regular annual session and may be called into special session if circumstances warrant.

The executive power of the *verbindung* rests with a central executive committee, the personnel of which is selected by the *aerztekammer* from among the physicians of the *verbindung*.

Decisions of the *aerztekammer* become binding on the entire membership of the *verbindung* if within two months of their announcement no objection has been raised by at least three cantonal organizations. The *Verbindung der Schweizer Aerzte* is concerned only with those political questions which in some way involve the profession. Now and then such questions may have economic implications. The actual protection of the medical profession's economic interests in the narrowest and most literal sense of the term is the function of the *Aerztesyndikat für die Wahrung wirtschaftlicher Interessen* (Syndicate for Protection of the Economic Interests of Physicians). Membership in the *verbindung* carries with it automatically membership in the syndicate. The *verbindung* is a nonprofit association in the eyes of the civil code, while the syndicate, because of its economic activities and the extent of its financial interests, is organized along the lines of a business corporation. The syndicate protects the interests of the physicians in dealings with medical supply houses and their organizations, procures privileged contracts with the insurance societies, functions as a collection agency, provides legal counsel and handles all economic questions which may be referred to it by the central executive committee of the *verbindung*.

Finally, there is the Swiss Physicians' Old Age and Life Insurance Society, founded Jan. 31, 1926. Any doctor who belongs to the *verbindung* and the syndicate may become a member and, by virtue of mutual agreements, members of the Society of Swiss Veterinarians and members of the Swiss Dental Association are considered eligible. In evaluating the importance of old age insurance and life insurance for the Swiss doctor, the syndicate has been influenced by the consideration that not so long ago the physician was scarcely in a position to save money without a certain compulsion being exercised. A holding in the insurance society, however, meant a compulsory putting by of at least 100 francs a year. This old age and life insurance society forms an integral part of professional organization.

The *Verbindung der Schweizer Aerzte* maintains as an adjunct its own legal tribunal a medical council of honor for the adjudication of internal disputes.

The *Schweizerische Aerztezeitung*, founded in 1920, serves as official organ of the entire medical profession. It endeavors to keep the physician informed on current medical topics and also contains news of the national and cantonal organizations. The price of subscription is included in and amounts to some 12 per cent of the annual (*verbindung*) dues.

Various procedures govern the payment of dues. The syndicate exacts nothing in the way of contributions from its membership. Since it is incorporated for profit and has to date limited itself to strictly business transactions, it can afford to waive any special levy on its members. The *verbindung* requires annual dues of 30 francs from its regular members. For physicians in official positions this amount is reduced to 15 francs, and the cantonal societies may obtain reductions for other doctors in special circumstances (beginning practice, withdrawing from practice and so on). Doctors purchasing old age and life insurance are permitted to choose among many differently regulated types of insurance; annual payments may be anywhere from 100 to 2,000 francs.

The *Verbindung der Schweizer Aerzte* numbered 3,368 regular members in 1935; including extraordinary (or special) members the figure is 3,987.

Of the authoritative rulings of the *aerztekammer*, some are worthy of mention: With regard to the factory physician, for example, although his importance as custodian of the worker's health is acknowledged, the chamber forbids him to hold office hours for therapeutic counsel. Such a procedure, it is held, is counter to the present-day concept of the patient's free choice of a physician. For a doctor to hold regular consultation hours away from his own residence and in a locality where one or more other doctors are already practicing is deemed a breach of professional ethics, especially if unjustified by a prolonged residence in the locality or by some manifest public need.

The next topic discussed is "The Regulation of the Specialization Question." In the last few years, an increasing number of rulings have been made with regard to specialization. The present arrangement is somewhat as follows: A specializing physician may work in his particular department either exclusively or incidentally; he may use at the same time the title of a specialist and that of a general practitioner. Use of this double nomenclature, however, may be forbidden by the cantonal medical societies.

As specialties only the following fields are officially recognized: surgery, dermatology, obstetrics, gynecology, internal medicine (with its particular subdivisions such as heart, lungs, stomach, intestine, metabolism), neurology, ophthalmology, orthopedics, otorhinolaryngology, pediatrics, psychiatry, radiology, tropical medicine, urology and venereology. To obtain the authorized title of "*spezialarzt*" (specializing physician) a doctor must have received special training in a medical establishment of high enough rating to guarantee an adequate preparation. Prerequisites of special training are as follows for the various fields: surgery four years (one year of which must represent training in another branch of medicine); dermatology two years plus one year in a second field; obstetrics four years plus one year in a second field; gynecology the same as for obstetrics; internal medicine with its subdivisions two years plus one year in a second field; neurology as a single specialty two and one-half years' study at a neurologic institute of university rank plus one-half year at a psychiatric clinic besides one year of additional study, half of which is to be spent in a medical clinic (that is, a clinic of internal medicine); ophthalmology three years of special preparation plus a recommended but not obligatory one year's study in a second field; orthopedics two years plus two additional years of surgery; otorhinolaryngology four years, of which at least two years is to be devoted to special training in this field and from one to two of the remaining years to the study of a second field; tropical medicine no particular stipulation, each case to be judged according to expediency; urology two years plus one year in a second field; venereology the same as for urology. These requirements are subject to modification in exceptional cases if the candidate succeeds in passing a special examination.

The customary procedure is for the central executive committee of the *Verbindung der Schweizer Aerzte*, with the approval of the society that represents the special field in Switzerland, to confer on all candidates completing one of the courses of training indicated above the title of "*spezialarzt*." Moreover, a doctor is permitted to specialize simultaneously in certain combinations of fields: surgery and gynecology, obstetrics and gynecology, dermatology and venereology, psychiatry and neurology.

On the other hand the Swiss *aerztekammer* has declined to recognize as special branches of medical science "forensic medicine," "laboratory research," "psychotherapy" and "tuberculosis." The rejection of the last named, "tuberculosis," means that work in the field of that disease is not regarded as constituting a separate category but rather as coinciding with the work of a recognized special sphere such as internal medicine (pulmonary diseases) or surgery.

## Marriages

DANIEL J. SULLIVAN, Trenton, N. J., to Miss Anne E. McKann of Samos, Va., in Washington, D. C., May 30.

GLEN WARD LEE, Anderson, Ind., to Miss Edith Anne Hoopingarner of Indianapolis, May 9.

MAX MARTIN GOULD to Miss Frances Matilda Schenker, both of Hartford, Conn., May 24.

HERMAN T. COMBS to Miss Mildred Ruth Long, both of Evansville, Ind., May 12.

CHARLES F. SCHNEE to Miss Ada Daniel, both of Maspeth, N. Y., May 20.

## Deaths

Frederic William Baldwin ♂ Danvers, Mass.; Harvard University Medical School, Boston, 1886; past president of the Essex South District Medical Society; formerly chairman of the board of health of Danvers; aged 74; one of the founders and on the staff of the Hunt Memorial Hospital; on the staff of the Beverly (Mass.) Hospital, where he died, March 7, of thrombophlebitis and pulmonary embolism.

Henry Harve Look, Kansas City, Mo.; Marion-Sims College of Medicine, St. Louis, 1899; member of the Missouri State Medical Association; formerly assistant professor of ophthalmology, University of Kansas School of Medicine, Kansas City, Kan.; served during the World War; for many years on the staff of St. Joseph Hospital; aged 59; died, March 14, of pneumonia.

Robert Aurand Allen ♂ Major, M. C., U. S. Army, Fort Wadsworth, N. Y.; Northwestern University Medical School, Chicago, 1906; served during the World War; entered the medical corps of the U. S. Army as a major in 1920; aged 58; died, February 8, in the Walter Reed Hospital, Washington, D. C., of myeloma and nephritis.

George E. Davis, West Mansfield, Ohio; Eclectic Medical Institute, Cincinnati, 1895; member of the Ohio State Medical Association; past president of the Logan County Medical Society; a member of boards of education in various towns; aged 75; died, March 20, in the Mary Rutan Hospital, Bellefontaine, of erysipelas.

Millard F. Hussey, Sidney, Ohio; Medical College of Ohio, Cincinnati, 1891; for many years a member of the board of education; at one time superintendent of the Lima (Ohio) State Hospital; formerly chief of staff of the Wilson Memorial Hospital and physician for the Shelby County Home; aged 79; died, March 12.

William Edward Knewstep ♂ Hampton, Va.; Medical College of Virginia, Richmond, 1911; formerly secretary of the Elizabeth City and County Medical Society; served during the World War; on the staff of the Dixie Hospital; aged 46; died, March 24, in the Johns Hopkins Hospital, Baltimore, of military tuberculosis.

Frank Thomas De Lano ♂ Rockville Centre, N. Y.; Albany Medical College, 1883; in 1904 served as president of what was then known as the Queens-Nassau Medical Society; for many years president of the bank, board of education, and public library; aged 79; died, March 28, of diabetes mellitus.

Alfred Henry Heald ♂ Berkeley, Calif.; University of California Medical School, San Francisco, 1931; instructor in pathology and roentgenology at his alma mater; on the staff of the Mills Memorial Hospital, San Mateo; aged 38; died, March 12, of cerebral embolus and chronic heart disease.

Frank Hayes Johnson, Carrizozo, N. M.; Chattanooga (Tenn.) Medical College, 1903; member of the New Mexico Medical Society; vice president of the state board of medical examiners; formerly county health officer; served during the World War; aged 53; died, March 19, of pneumonia.

William Cotman Whitmore ♂ Major, M. C., U. S. Army, Governors Island, N. Y.; Medical School of Maine, Portland, 1909; served during the World War; entered the medical corps of the U. S. Army as a lieutenant in 1917 and in 1929 was appointed a major; aged 51; died, April 17.

John Howard Johnson, Windermere, Fla.; Cleveland University of Medicine and Surgery, 1897; at one time a practitioner in Wauseon, Ohio, where he was a member of the board of education and county coroner; formerly mayor of Windermere; aged 62; died, March 20.

Milo Ruben Hewitt, Hartland, Wis.; Bellevue Hospital Medical College, New York, 1869; professor of obstetrics at the Milwaukee Medical College, 1894-1897; formerly on the staff of the Milwaukee County Hospital; aged 91; died, March 8, of bronchopneumonia.

George Sawyer Pitcher, Hampton, Va.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; veteran of the Spanish-American War; for many years connected with the U. S. Public Health Service; aged 72; died, March 8.

Robert Lee Harris ♂ Cleburne, Texas; Marion-Sims College of Medicine, St. Louis, 1896; past president and secretary of the Johnson County Medical Society; owner and medical superintendent of the Cleburne Sanitarium; aged 69; died, February 9, of pneumonia.

Thomas Ellis Drewry, Griffin, Ga.; Atlanta Medical College, 1887; Jefferson Medical College of Philadelphia, 1890; member of the Medical Association of Georgia; aged 75; died, March 18, in the Strickland Memorial Hospital, of coronary occlusion.

Verner Paul Johnson ♂ Delano, Minn.; University of Minnesota Medical School, Minneapolis, 1927; president of the Wright County Medical Society; aged 34; died, March 18, in the Fairview Hospital, Minneapolis, of acute lymphatic leukemia.

Albert Fredrick Heising ♂ Menomonie, Wis.; St. Louis Medical College, 1890; past president of the Dunn County Medical Society; aged 70; died, March 27, in St. Joseph's Hospital, St. Paul, of carcinoma of the rectosigmoid with metastasis.

Addison Barrett Housholder, Lovettsville, Va.; University of Maryland School of Medicine, Baltimore, 1893; member of the Medical Society of Virginia; on the staff of the Frederick (Md.) City Hospital; aged 66; died, March 20, of heart block.

Stanley R. Hare, Batavia, N. Y.; Syracuse University College of Medicine, 1920; member of the Medical Society of the State of New York; on the staff of St. Jerome's Hospital; aged 39; died, March 26, of gastric ulcer and hemorrhage.

Frank J. Flannery, Baltimore; University of Maryland School of Medicine, Baltimore, 1880; for many years resident physician at the Mount Hope Retreat; aged 77; died, March 11, in St. Agnes' Hospital, of carcinoma of the prostate.

Jefferson Gould, Fenton, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888; member of the Michigan State Medical Society; aged 84; died, March 21, of cerebral hemorrhage and arteriosclerosis.

Harry Cannon, San Diego, Calif.; Washington University School of Medicine, St. Louis, 1904; formerly state senator in Minnesota; aged 63; died, March 23, in the Mercy Hospital, of coronary occlusion, arteriosclerosis and hypertension.

Otto Herman Friedemann, La Grange, Ill.; Rush Medical College, Chicago, 1927; member of the Illinois State Medical Society; aged 38; died, March 29, in the Albert Merritt Billings Memorial Hospital, Chicago, of coronary occlusion.

Samuel J. Firestone, Cleveland; Fordham University School of Medicine, New York, 1916; served during the World War; on the staff of the Mount Sinai Hospital; aged 43; died, March 3, in the Cleveland Clinic, of pneumonia.

William McClure Leslie ♂ Blackwell, Okla.; Baylor University College of Medicine, Dallas, Texas, 1916; owner of a sanatorium bearing his name; aged 46; died, March 25, of streptococcal infection of the blood stream.

Richard Deyo Dugan, Springfield, Ill.; Missouri Medical College, St. Louis, 1899; member of the Illinois State Medical Society; served during the World War; aged 59; died, March 23, of coronary thrombosis.

Herman Christian Galster, Erie, Pa.; Cleveland Medical College, 1892; member of the Medical Society of the State of Pennsylvania; aged 73; died, March 17, in St. Vincent's Hospital, of hypertensive heart disease.

David Herbert Richardson, Celina, Ohio; Starling Medical College, Columbus, 1869; Medical College of Ohio, Cincinnati, 1879; member of the Ohio State Medical Association; aged 87; died, March 20, of heart disease.

Thomas Eggleston Burrows, Surrey, England; University of the City of New York Medical Department, 1877; L.K.Q.C.P., Dublin, Ireland, 1887; died, March 8, in Sherborne, N. Y., of bronchopneumonia and arthritis.

**Wenceslaus J. Hovorka**, St. Paul; Medical Department of Hamline University, Minneapolis, 1897; aged 78; died, March 27, in the Midway Hospital, following transurethral prostatectomy and osteomyelitis pubis.

**Peter N. Hoover** ☉ Boonville, Ind.; Kentucky School of Medicine, Louisville, 1881; past president of the Warrick County Medical Society; aged 84; died, March 31, of cardiac insufficiency and influenza.

**Dildy McCowan Austin** ☉ Belen, N. M.; Tulane University of Louisiana School of Medicine, New Orleans, 1930; aged 30; died, March 28, in St. Joseph's Hospital, Albuquerque, of amylal poisoning.

**Benjamin Franklin Cain**, Cincinnati; Marion-Sims College of Medicine, St. Louis, 1899; Medical College of Ohio, Cincinnati, 1900; aged 67; was found dead in bed, March 27, of heart disease.

**William James Hardy**, Belmont, N. Y.; New York Homeopathic Medical College and Hospital, 1889; formerly member of the board of education; aged 74; died, March 14, of myocarditis.

**John Fred Gordon**, Otway, Ohio; University of Louisville (Ky.) Medical Department, 1894; member of the Ohio State Medical Association; aged 66; died suddenly, March 27, of heart disease.

**Arthur Levi Knight** ☉ Cincinnati; Miami Medical College, Cincinnati, 1890; aged 69; formerly on the staff of the Good Samaritan Hospital, where he died, February 29, of lobar pneumonia.

**Frank Bozeman King**, Houston, Texas; Kentucky School of Medicine, Louisville, 1885; member of the State Medical Association of Texas; aged 72; died, March 14, in St. Joseph's Infirmary.

**Frank L. Baker**, Burlington, W. Va.; College of Physicians and Surgeons, Baltimore, 1889; member of the West Virginia State Medical Association; aged 74; died, March 24, of cerebral embolism.

**James Blain Hannah**, Addyston, Ohio; Medical College of Ohio, Cincinnati, 1885; member of the Ohio State Medical Association; aged 79; died, February 19, of coronary thrombosis.

**Frederic Theodore Underhill**, Vancouver, B. C., Canada; L.R.C.P., Edinburgh, 1881; F.R.C.S., Edinburgh, 1884; D.P.H., R.C.S., Edinburgh, F.P.S., Glasgow, 1897; died, February 17.

**Enrico Raffaele Gnasso** ☉ Fort Lee, N. J.; Birmingham (Ala.) Medical College, 1913; medical advisor for the local board of health; aged 55; died, March 22, of coronary sclerosis.

**Horace Winter Miller**, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1889; aged 70; died, March 6, of bronchopneumonia and mitral insufficiency.

**Charles Tom Cook Wilson**, Champaign, Ill.; Cincinnati College of Medicine and Surgery, 1890; aged 67; died, March 24, in the Carle Memorial Hospital, of cerebral hemorrhage.

**George W. Ragsdale**, Hiram, Ga.; University of Georgia Medical Department, Augusta, 1902; past president of the Paulding County Medical Society; aged 58; died, March 25.

**Samuel Holt Toy**, Umatilla, Fla.; Kentucky School of Medicine, Louisville, 1882; member of the Florida Medical Association; aged 85; died, February 24, of arteriosclerosis.

**George Nelson Drysdale**, Crescent City, Calif.; Halifax Medical College, Halifax, N. S., Canada, 1891; fellow of the American College of Surgeons; aged 69; died, March 15.

**Edward F. De Vaux** ☉ Fort Wayne, Ind.; American Eclectic Medical College, Cincinnati, 1893; aged 76; died, March 8, of myocarditis, diabetes mellitus and infective arthritis.

**John Tandy Stewart** ☉ Indianapolis; Eclectic Medical College, Cincinnati, 1928; on the staff of the Methodist Episcopal Hospital; aged 34; died, March 9, of chronic myocarditis.

**Norman W. Gustine**, Cleveland, Texas (registered in Texas by the State Board of Medical Examiners, under the Act of 1907); aged 81; died, in March, of heart disease.

**G. W. Nelson**, Marshallville, Ga.; College of Physicians and Surgeons, Baltimore, 1882; member of the Medical Association of Georgia; aged 73; died suddenly, February 26.

**Stanley Arnold Seigle**, Wyncote, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1932; aged 26; died, March 27, of Hodgkin's disease and cerebral embolism.

**James Marion Kerns**, Malad City, Idaho; Hospital College of Medicine, Louisville, Ky., 1898; served during the World War; aged 58; died, March 9, of cerebral hemorrhage.

**Henry Stokes Lott**, Winston-Salem, N. C.; University of Georgia Medical Department, Augusta, 1884; aged 75; died, March 28, of arteriosclerosis and cerebral hemorrhage.

**Oscar W. Brandon**, Pima, Ariz.; Central College of Physicians and Surgeons, Indianapolis, 1896; member of the Arizona State Medical Association; aged 63; died, February 26.

**James Henry Lancashire**, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1883; died, March 6, in St. Augustine, Fla.

**Horace Landes Kulp**, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1895; aged 64; died, March 22, of cerebral hemorrhage and hypertension.

**T. J. Garner**, Washington, Ark.; Atlanta Medical College, 1884; aged 76; died, March 13.

## Bureau of Investigation

### HEALTH REMEDY PRODUCTS

#### "Health Anti-Tobacco" and "Health Anti-Liquor" Fraud Debarred from the Mails

From Kansas City, Mo., the Health Remedy Products exploited its mail-order tobacco and liquor "cures." The so-called "anti-alcoholic treatment" was typical of the age-old "can-be-given-secretly-at-home" buncombe, and the "new, easy and quick" tobacco "cure" was a fit companion. Fortunately, this duo of deceptions enjoyed a brief if profitable existence.

Initiated in 1933, it came to an abrupt demise in March 1936 on the declaration of the Postmaster General that the promoter, one G. S. Muchemore, had led the public to anticipate far more than the United States postal authorities deemed credible.

The Postmaster General has stated officially that the Health Remedy Products, G. S. Muchemore, Secretary, and their officers and agents as such, were engaged in conducting a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. In view of this, the postmaster at Kansas City, Mo., was instructed to mark "Fraudulent" and return to the senders all letters addressed to the Health Remedy Products and to refuse to pay any postal money orders to the concern.

The Health Remedy Products was conducted by the aforementioned Muchemore, sole owner, with the assistance of one female employe. Victims were secured by means of advertisements (of the we-want-to-help-you type) printed in numerous newspapers and periodicals. Typical advertisements of the tobacco and liquor nostrums read:

**QUIT WHISKEY**

The Health Remedy Products of Kansas City is now offering a NEW scientifically prepared treatment to aid men and women banish all desire for drinking. Thousands have already proved success of this New Easy Way. Can be given secretly. Write today for Free Booklet. Accept no substitutes. Write.

**Health Remedy Products** 2453 Manufacturers Exch. Bldg. KANSAS CITY, MO.

**QUIT TOBACCO**

The Health Remedy Products of Kansas City is now offering a NEW scientifically prepared treatment to aid men and women banish quickly all desire for smoking, chewing or snuff. FREE Thousands have already proved success of this New Easy Way. Write today for Free Booklet. Accept no substitutes. Write **HEALTH REMEDY PRODUCTS, Dept. 548, Manufacturers Exch. Bldg., Kansas City, Mo.**

The inquirer who succumbed to the lure of a Quit-Tobacco or Quit-Liquor advertisement received a lengthy printed form-letter. The liquor "come-on" letter read in part:

"Your letter of inquiry about the Health Anti-Liquor treatment has been received.

"It is a pleasure for me to write to one who is sincere in wanting to quit the drink habit, or is trying to help someone else who has not the will power to try and do this themselves, and I want to do what I can to help you by telling you about the wonderful easy way to take Health Anti-Liquor treatment which so many people say has helped them quickly leave off from all desire of drinking . . ."

Although the promoter inferentially implies in his letter to the prospective victim that he had been a liberal imbibor of alcohol until saved by the "new and easy mixture," he confessed to the post office inspector who investigated the case that he had never taken the "treatment." The letter further stated that "drunkenness is a monster that steals both health and money"; it might well have truthfully added that the Health Remedy Products was equally proficient in achieving a similar result. The Anti-Liquor circular declared its treatment to have been discovered many years ago by an old German physician (the name of this eminent person was not given). Somehow it is usually an Indian chief or an old German physician!

Wives, mothers and sweethearts were assured that the "cure" could be administered secretly. The Bureau of Investigation, in similar exposés, has repeatedly called attention to the fact that there is no drug or combination of drugs known that may be administered either secretly or with the patient's knowledge that will "cure" the desire for alcohol. The principal causative factors in the urge for alcohol are psychic. All methods toward rehabilitation are doomed to failure unless the mental conflicts are removed which bring about the desire to escape from reality by means of the alcoholic "spree." There is no sovereign remedy that will supply will power where none exists.

Front cover of a Health Remedy Products circular (greatly reduced).

If the prospective victim seemed reluctant to part with his money for the "reliable and scientific" old German discovery, Mr. Muchemore became so perturbed that he sent form-letter number two. In this epistle the exploiter expressed a righteous indignation that his desire to aid suffering humanity had failed to meet with a prompt remittance. "I felt sure," he scolds, "that you were serious in wanting to free someone from one of the most terrible curses in the world today, and I only hope that you have not weakened [italics ours] from this thought."

To make doubly sure that the victim did not weaken, the trap was cunningly baited with the usual "patent medicine" money-back guarantee. To the unsuspecting the proposition sounded extremely honest and straightforward. All the unfortunate prospect had to do was to take the medicine as directed and then give the "treatment" time to work. If the same old urge to drink returned, all that was necessary was simply to write the Health Remedy Products' office and the money would immediately be returned in full. Just how long an interval Mr. Muchemore felt should be allowed for the treatment to work was not stated; people who claimed they had tried the "Health Anti-Tobacco Treatment" without securing the promised results, failed to get their money back after requesting the promoter to refund it.

While Mr. Muchemore claimed that the Health Remedy Products' Anti-Liquor Treatment was a "new, reliable and scientific method" of treating drunkenness, the post office authorities stated that, according to chemical analysis, the stuff consisted of the "acorns of white oak, roasted, ground and combined with about twenty per cent alcohol by volume," and that the principal therapeutic agent of this preparation was nothing more than tannin from the acorns.

Whether the same "doctors and chemists" who were so eager to aid men and women to quit the liquor habit had another spasm of scientific altruism and compounded the anti-tobacco nostrum, the advertising matter does not state. However, chemical analysis, according to the postal authorities' report, disclosed this "new scientifically prepared treatment" to be "composed essentially of lobelia, nux vomica, gypsum, milk sugar, capsicum, ipecac, powdered elm bark, licorice and corn starch." They left out the "kitchen stove"!

These worthless nostrums, stripped of their advertising falsifications, stand convicted as more heartless demonstrations of the iniquity of the "patent medicine" business, whose callous indifference to truth has caused untold suffering among people who can ill afford such treachery.

## Correspondence

### BRADYCARDIA WITH HYPOGLYCEMIA

To the Editor:—Ormond (THE JOURNAL, May 16, p. 1726) says he has not been able to find reports of the occurrence of bradycardia with hypoglycemia.

Manfred Sakel has reported many such observations in the course of his insulin shock treatment of schizophrenia. His publications are a valuable source of data on the clinical manifestations of hypoglycemia. In his monograph "Neue Behandlungsmethode der Schizophrenie," for example (Vienna, Verlag von Moritz Perles, 1935) he states (p. 9) that "a very marked bradycardia sometimes reaching thirty-four beats a minute is characteristic of uncomplicated progressive hypoglycemia." But where there is a strong compensatory epinephrine reaction, or convulsions, he correctly observes, the cardiac response is different.

JOSEPH WORTIS, M.D., New York.

### POTENCY OF ANTIANEMIC PREPARATIONS

To the Editor:—The editorial on the potency of antianemic preparations in THE JOURNAL, April 11, prompts me to comment on the obvious inadequacy of the method for determining the quantitative potency of liver substitutes prescribed by the Council on Pharmacy and Chemistry.

Determination of the potency of such substances, as specified by the Council, is to be made on the basis of the magnitude of the reticulocyte response induced by the administration of the liver substitute. Although such a response has been used as an indication of qualitative potency of liver and substitutes for it since the introduction of liver therapy, it has been almost uniformly recognized that the magnitude of this response is not necessarily a measure of the power of a substance to produce erythrocytes, which is the fundamental problem concerned in the treatment of pernicious anemia. Not only will certain substances not effective in stimulating erythrocytes produce a reticulocyte increase, but it has been adequately demonstrated that a maximum or satisfactory reticulocyte response may be induced quite as well by such a small amount of liver substance that only a subminimal erythrocyte increase will be induced as by means of a much greater amount of potent substance which will produce an optimal erythrocyte increase.

Sufficient data are now available in both our own and foreign literature based on initial erythrocyte responses to liver therapy administered in various ways, and on maintenance requirements, so that the efficacy of the liver substitutes may be readily and relatively accurately evaluated on a quantitative basis. In fact, published data indicate that both here and abroad evaluations of potency have been made not alone on the basis of the magnitude of the reticulocyte rise but on the basis of the initial erythrocyte increases, usually during a period of one month, and/or the maintenance requirements in all but one large clinic.

The editorial in one place makes the following comment: "The foregoing illustrates the confusion that is possible in estimating comparative antianemic potencies and emphasizes the necessity for standards such as the Council on Pharmacy and Chemistry has devised." Had the Council initiated standards for determining "comparative antianemic potencies" based on evaluation of the efficacy of substitutes for liver to produce erythrocytes and to maintain them at a normal level instead of resorting to a method open to all sorts of variation and interpretation, the problem of evaluating the efficiency of one particular extract would not have assumed the almost colossal proportions which it has.

It is hoped that the committee on revision of the Pharmacopeia will benefit from the experience of the Council and that the evaluation of the various liver substitutes for inclusion in the new edition may be made on the basis of their effect on erythrocyte production and maintenance.

WILLIAM P. MURPHY, M.D., Boston.

### INCIDENCE OF CESAREAN SECTION

To the Editor:—In a paper on the training of medical students in obstetrics (THE JOURNAL, April 25, p. 1435) I inadvertently committed an error in comparing the incidence of cesarean section in American with foreign institutions. It was stated that the incidence at the Boston Lying-In Hospital was 1 to 12 and at the Jefferson Hospital in Philadelphia 1 to 6 during the period 1929-1930. Dr. Frederick C. Irving, visiting obstetrician to the Boston Lying-In Hospital, and Dr. P. Brooke Bland, attending obstetrician to the Jefferson Medical College Hospital of Philadelphia, have each protested the correctness of my statements. Dr. Irving informs me that the incidence of cesarean section at his institution was 1 in 32.7 in 1929 and 1 in 27.5 in 1930, while Dr. Bland states that during the period from 1925 to 1935 the percentage has been 1.6, or less than one in fifty deliveries. While I regret any offense or injustice that might be attributed to my statements, may I state that my figures were obtained from the Report on Maternal Mortality in New York City, 1930-1932, made and published by the New York Academy of Medicine. I find on further investigation that tabulations on the incidence of cesarean section in the United States, from which the Academy Report figures evidently were derived, appeared in the following articles: Davidson, A. H.: *Irish J. M. Sc.*, December 1931, pp. 642-654. Miller, C. J.: *Surg., Gynec. & Obst.* 48:745 (June) 1929. Gellhorn: *Progressive Medicine* 3:93 (Sept.) 1930.

Following the receipt of the protests I made an effort to locate the original sources of the statistics noted in Dr. C. Jeff Miller's paper but was unable to do so. In a letter subsequently published in *Surgery, Gynecology and Obstetrics* (50: 512 [Feb.] 1930) in which he acknowledges the error, Dr. Miller states that he quoted from a source which he had every reason to believe accurate and reliable.

Evidently an error has been committed by the publication of statistics from the two hospitals in question which are palpably false and I regret very much having become involved in their further dissemination. However, I have been led to a further search and find that, unfortunately, there are other centers of obstetric activity in this country from which equally high cesarean incidences were reported. I will refrain, however, from any further discussion of this subject at the present time and merely desire to reaffirm my regret for having included the two hospitals referred to in the contention expressed in my paper; namely, that the incidence and consequent mortality associated with cesarean section is much too high in this as compared with other countries.

GEORGE W. KOSMAK, M.D., New York.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### DIAGNOSIS IN DISORDER OF NERVOUS SYSTEM

*To the Editor:*—A woman, aged 53, highly nervous, complained of inability to move either foot and loss of sensation in same. I saw the patient March 14, two days after the onset of the complaint. The previous history was essentially negative, except that she had a scare the day before the onset of the complaint. Physical examination showed both feet dropped, and inability to flex the feet or ankles or to move the toes. The muscles in the calves of both legs were apparently flaccid. There was no sensation to pin pricks on the lateral aspect of both feet; sensation was intact above the ankles and on the medial aspects of the feet. Sensitivity of the soles of the feet could not accurately be determined because of callus. Deep muscle and joint temperature sensation was intact in all areas. Patellar reflexes were slightly diminished but equal. Babinski and Gordon reflexes and ankle clonus could not be elicited. The heart was fibrillating. The blood pressure was 250 systolic, 120 diastolic. Blood analysis showed: hemoglobin 55 per cent; red blood cells 3,100,000. The red cells were well formed, with no poikilocytosis or anisocytosis. The sugar content was 0.201. Analysis of the urine revealed 1.4 per cent sugar. Since she was first seen the patient has regained movement and sensation in the right foot. There is slight improvement in sensation of the left foot and the patient claims that she can feel slight muscle movement in the left foot, but this is not apparent to the examiner. For the past few days she has complained of numbness and tingling of both feet and of the left hand. The blood pressure has fluctuated between 260 and 220 systolic with diastolic at 120. Any suggestion in diagnosis and therapeutics in this case would be greatly appreciated. Please omit name. M.D., Long Island.

*ANSWER:*—While the onset of a paralysis in a nervous patient following fright and the failure of changes to group themselves in typical fashion suggest hysteria, the impression is one of organic disability. Ordinarily in hysteria, if anesthesia accompanies paralysis, the two generally cover the same area.

The rapid onset is suggestive of a vascular basis, and with a fibrillating heart the possibility of multiple embolisms exists. Should this be responsible, one would expect a change in the color and temperature of the affected extremities and interference with the pulsation of the dorsalis pedis and posterior tibial arteries and possibly of the left ulnar and radial arteries. When sensory changes accompany such an infarctive paralysis they are usually more of the stocking and glove type than was observed here, and there is usually a considerable element of pain. In a case of a few hours' duration, papaverine, through relaxation of the collateral circulation, is of benefit, but it is not helpful at a later stage.

A peripheral neuritis would hardly make its appearance so abruptly, and the sensory changes are hardly in keeping with the muscular involvement. Was the Achilles tendon reflex absent?

A lesion of the spinal cord in the segments subserving the distribution of the fourth lumbar to the second sacral nerve, as judged by the paralysis, or of the first sacral, as judged by the disturbance in sensation, is also suggested. With the changes noted the disorder would suggest a radicular involvement, which also is not in keeping with the sudden onset. A lesion within the cord itself, such as a hemorrhage, which is not a common occurrence, could be the cause, but the hamstring muscles, the gluteus maximus and medius, and the rotators of the thighs would probably be involved as well. A larger lesion would interrupt the function of the lower part of a cord. A perianal area of sensory disturbance easily escapes detection, but the sphincters were presumably intact. Examination of the spinal fluid may be helpful, should the development of the case be in keeping with such a possibility. In this event the paresthesias in the left arm would remain unexplained.

An unlikely possibility is a bilateral cerebral lesion at the tops of the Rolandic fissures. In these cases the disorder is usually on the venous side of the circulation; Jacksonian attacks are usually present, and Babinski's sign is usually positive.

The hypertension and the increased blood sugar would seem to have laid the foundation of the disorder but are hardly immediately responsible. These should be treated with due care and as far as it is possible. Heat applied to the extremities would be a safe recommendation, it being borne in mind that a sensory disturbance exists and that care must be exercised to prevent a burn.

### SPINAL FLUID IN SYPHILIS

*To the Editor:*—What is the proper interpretation of a spinal fluid examination in regard to syphilis? Please discuss: 1. Cell count. 2. Globulin. 3. Colloidal Gold. 4. Pressure. How should these findings be evaluated? Please omit name. M.D., Pennsylvania.

*ANSWER:*—1. Normally there are from 3 to 7 cells per cubic millimeter. A moderate increase in cells, from 10 to 100, with the lymphocytes predominating is found in all forms of neurosyphilis. An increase in cells to 1,000 with lymphocytes predominating is also found in acute syphilitic meningitis.

2. Normally cerebrospinal fluid contains from 15 to 45 mg. of protein per hundred cubic centimeters of fluid. This amount gives a negative test for globulin as usually made. This protein consists mostly of albumin with a small amount of globulin. In most conditions, protein and cell increase go together. Occasionally one may increase more than the other, giving dissociated values. A slight increase in globulin, at 1+ reaction, is found in neurosyphilis. A moderate increase in globulin, a 2+ reaction, may occur in dementia paralytica. A great increase in globulin, 3+ or 4+ reaction, is found in spinal or cerebrospinal meningitis, especially of the syphilitic and epidemic types.

3. Normal cerebrospinal fluid does not precipitate any of the colloidal gold. A strong reaction in low dilutions is known as a paretic curve and is characterized by a 5554321000 curve, but may be weaker. It may be present in dementia paralytica, secondary syphilis, meningovascular syphilis, tabes dorsalis, multiple sclerosis and brain tumor. A strong reaction in medium dilutions is known as the tabetic or luetic curve and is characterized by a 0244310000 curve. It occurs most often in tabes dorsalis, meningovascular syphilis and poliomyelitis. A strong action in high dilutions is known as a meningeal curve and is characterized by a 0011222333 to a 0000245530 curve. It is found in practically all the acute meningitides.

4. The normal cerebrospinal fluid pressure is from 100 to 150 mm. of water when the patient is lying on the side, and from 200 to 300 mm. of water when the patient is sitting up. The pressure is increased in cerebral syphilis. Clear fluid is obtained in central nervous system syphilis. Occasionally xanthochromic fluid is also obtained in meningovascular syphilis.

### INDUSTRIAL DISEASE

*To the Editor:*—A man of 48, who has always been strong and wiry, complains of a gradual increasing weakness of a year's duration. He also has a sensation of epigastric fullness and weakness, especially with exertion. He has nausea frequently in the morning, yet he never vomits. These symptoms do not seem to be connected with meal time or food in any way. A precordial oppression is often associated with the epigastric fullness, yet this has been relieved considerably with belladonna. There is no constipation and the stools have been unformed for a year. At times he has noted undigested food particles in the stools. He is losing weight gradually and his appetite has vanished. Although he was said to have pulmonary tuberculosis fifteen years ago, there have been no pulmonary symptoms in years. Physical examinations have been repeatedly negative. The heart and lungs and the possibility of a neurosis have been ruled out clinically to my satisfaction. Laboratory examinations have given results within normal limits. The white blood cells number 7,300, red blood cells, 4,700,000, hemoglobin 75 per cent. The urine is normal. The stools are negative for parasites, yet they show undigested meat particles. Gastric analysis falls within normal limits. Sputum examination and the Kahn test are negative. The man works for a gas company and throughout the day he must go down into excavations and weld gas pipes with an acetylene torch. He uses no mask. Could the latter fact have any bearing on this case? Kindly omit name. M.D., Florida.

*ANSWER:*—It is a safe rule in medicine regularly to be suspicious of the unusual. Applying this rule to the present instance, there probably are many more causes of this condition unrelated to work than to the contrary. There are, however, a few possibilities, and these are now mentioned. In carrying out welding work in excavations or enclosed areas, the hazards are greater than would obtain in open air conditions. Various metal fumes are created, together with the possibility of carbon monoxide gas. Remotely there is a possibility of the formation of sulfureted hydrogen or arseniureted hydrogen, due to impurities in the acetylene gas. This possibility is less now than in earlier years, as the result of more highly purified acetylene. The typical action of the gases and fumes produced by welding is on the respiratory tract. Severe pulmonary edema is possible and pulmonary hemorrhages probably may arise. Pneumonia among welders occurs at a higher rate than for workers in general. Gastro-intestinal disorders as the exclusive manifestation of the action of welding gases and fumes and in the absence of involvement of the respiratory tract would be unusual. In the case of welding on galvanized metals, gastro-intestinal disturbances are common and may arise in the absence of associated involvement of the respiratory tract. In metal fume fever

and zinc chills arising from exposure to zinc fumes, loss of appetite and nausea are almost constant manifestations among others. The precordial oppression mentioned in the query may be of significance and the gastric disturbance may stand in relation to a cardiac condition. It is reasonably well established that the gaseous products of welding may exert an unfavorable action on the heart. It is the intent of this discussion merely to point out that there may be certain possible connections between this patient's condition and his employment. But no warrant exists for a definite stand that the condition described may with certainty be laid to welding work as its primary cause.

#### DESQUAMATION IN MILD SCARLET FEVER

*To the Editor*—Is there any other disease besides measles, scarlet fever and exfoliative dermatitis that is characterized by exfoliation? There was an epidemic here all summer of what some of us think is a mild scarlet fever, while others are calling it a streptococcal sore throat with a rash and exfoliation. Most of the patients were not sick enough to go to bed. The disease is characterized by a rather mild sore throat with slight redness or the typical blood red throat of scarlet fever, with a rather light rash of the abdomen of punctate type. Sometimes there is merely an edema of the skin with some erythema. Some patients have sore tongues and some have complained of soreness of the skin of the palms. Most of the patients have been ill for from four to five days with recovery and in a week or so there has been an exfoliation of the palms of the hands and tips of the fingers. The disease is more contagious than typical scarlet fever, often running through an entire family, but in no instance has an albuminuria followed. Most of the cases are not as severe as an attack of tonsillitis. Scarlet fever serum has been used twice and in one case gave a good result and in another case gave a questionable result. There have been one or two cases out of perhaps forty in which there was otitis media. Kindly omit name. M.D., Nevada.

**ANSWER**—German measles is sometimes followed by a fine branny desquamation. However, the desquamation of German measles is not observed on the palmar or plantar surfaces. Certain drugs, notably arsenic, may also produce either a mild or severe desquamation. Foods may act similarly in allergic individuals.

From the description it seems almost certain that the disease referred to is mild scarlet fever. It might further confirm the correspondent's opinion in this respect if Dick tests were made on all patients following their recovery. A very high percentage of negative Dick tests would be strongly suggestive that immunity had resulted from an attack of scarlet fever.

#### INJECTION TREATMENT OF HEMORRHOIDS AND HYDROCELE

*To the Editor*—Is sodium morrhuate 5 per cent a satisfactory drug to use in the injection treatment of internal hemorrhoids? What advantage has quinine and urea hydrochloride over sodium morrhuate or vice versa? How much time should elapse before an internal hemorrhoid can be re-injected? Can satisfactory results be obtained by the injection of sodium morrhuate or other drugs into a hydrocele of the tunica vaginalis testis and, if so, please outline the technic. Please omit name and post office address. M.D., Virginia.

**ANSWER**—A 5 per cent solution of sodium morrhuate is satisfactory for the injection of internal hemorrhoids in the absence of infection, fissures and fistulas. Occasionally a dilation of the sphincter may be necessary. Quinine and urea hydrochloride are more apt to produce necrosis. Patients sensitive to quinine may develop dangerous, occasionally fatal, reactions. Five per cent phenol in vegetable oil is favored by a great many proctologists. Much more important than the selection of the sclerosing solution is the proper selection of the suitable case, which requires a thorough understanding and recognition of the pathologic processes in the rectum. Injections may be made once or twice a week, depending on the reaction following injections.

The treatment of hydrocele by injections of sodium morrhuate is started by washing out the sac first with sterile physiologic solution of sodium chloride followed by the injection of from 4 to 5 cc. of the drug. To tap the sac the skin must be carefully sterilized with a suitable antiseptic. A dermal wheal is then produced with 1 per cent procaine hydrochloride and a spinal puncture needle is used to tap the sac. The fluid should be completely removed, care being taken that the needle still remains free in the cavity and is not caught in the wall of the sac.

Before deciding on the injection treatment of a hydrocele, gonorrheal, tuberculous or nongonorrheal epididymitis and a tumor of the testicle must be excluded. Such lesions may become palpable after the sac has been tapped. One must also make certain that there is no communication with the peritoneal cavity such as occurs in the congenital type of hydrocele and that there is no associated inguinal hernia. The latter may become irreducible if the hydrocele is obliterated.

#### HEADACHES AND MENSTRUATION

*To the Editor*—Mrs. W., aged 26, never pregnant, was never seriously ill in the past. She had a tonsillectomy and adenoidectomy in 1931 and an appendectomy in 1932. During her convalescence she developed a cystitis and pyelitis following catheterization. This condition lasted about five weeks and cleared up. She had two slight recurrences of the same malady but each time it cleared up quickly. Menstruation began when she was 14, the flow being markedly irregular until the time of her marriage, three and one half years ago. At all times the flow is very scanty, stringy and mucous; the last four months witnessed an exceedingly scant flow, lasting not even twenty four hours. The menses are painless. While in training to be a nurse she had a dilation and curettage and was given some "injections" with the hope that her flow might become more profuse and more regular, nothing was accomplished, however, beyond establishing a somewhat more regular flow. The patient had "terrific" reactions following the injections, and the latter had to be abandoned. During the appendectomy the patient's pelvic organs were examined and found normal (apparently). The family history is negative save for the fact that her mother had what doctors considered "migraine" headaches. The patient is a native of one of the Southern states and her headaches (the chief complaint) started with her coming east three and a half years ago. The following is her description of the headaches and what goes with it: "The headaches are severe, peculiar, irregular as to time of appearance, there being no particular cause that would start them. The headache begins at the root of the nose, spreads to the malar bones, and many times there is a sensation of 'pinching' in the back of the neck. The neck feels 'stiff' and is never relaxed. The pain then travels to the shoulders and to the spinal column halfway down. There is no nausea. There is a sensation as if the eyes 'pop' out of the orbits, and there is a constant desire to draw the head backward. There is a throbbing in the temples, and for more than a year with the headaches there was been a sharp, needle-like 'shooting' in any part of the body. This 'shooting' is of very short duration; it 'darts' through the part and ceases. These headaches leave me in a very weak condition and are followed by marked perspiration of the palms of the hands and the axillae." The patient lost 10 pounds within a year. She is very nervous and irritable and oftentimes is depressed. Her reflexes are exaggerated. The blood pressure is 112 systolic and diastolic. The eye-grounds are normal. The sinuses are normal. The blood picture is normal. The ninety skin tests for possible allergy were negative. There is no postnasal discharge. The last urine examination showed a specific gravity of 1.030, marked acidity, albumin, pus cells, many epithelial cells, many casts and many finely granular casts. Fehling's solution turns yellowish green on standing. Roentgen examination shows apparent osteomatous change in the right posterior ethmoid cell and unerupted, impacted third molar teeth. The teeth were extracted with no relief. The roentgen examination according to the eye, ear and nose man do not account for the headaches. The Wassermann test is negative. All urine examinations until the last were usually negative, but the specific gravity kept creeping upward, it started with 1.005 in 1932 and went up to 1.030 in 1935. Physical examination is negative save for the fact that of late the patient feels a dull pain along the path of the right ureter. Pressure over the shoulders, the back of the neck and along the sternocleidomastoid muscle reveals distinct pain. The physicians who have treated the patient are inclined to believe that there is a hysterical basis underlying the condition that accounts for all these symptoms. It is my belief, however, that there is apparently some organic lesion (not omitting the hysteria part), perhaps a hypofunctioning gland or glands, perhaps the ovary, as one may deduce from the menstrual history of the patient. I would greatly appreciate your kindness if you would give me your opinion regarding this case and, if possible, an outline for some course of treatment. Kindly omit name.

M.D., Connecticut.

**ANSWER**—The patient's own minutely detailed description of the character of her headaches would seem to lend some support to the suspicion that a hysterical element may exist, and yet there are other features of the case that call for investigation. No mention is made of the frequency of the headaches, but presumably their occurrence is not limited to any part of the menstrual cycle. It is unlikely that the hypomenorrhea, which is the only menstrual symptom, is a causative factor, though it should be of interest to make studies of the urinary hormone excretion, if this is practicable. The headaches do not suggest migraine, which is often preceded by an increased output of follicle stimulating factor. If other studies, to be mentioned, do not throw light on the problem, it would be permissible to try, experimentally at least, the hypodermic use of an estrogenic preparation, preferably one of the oily solutions. A dosage of about 2,500 international units two or three times a week could be tried throughout one cycle at least.

A rather significant statement is that the headaches date from about the time of a sharp postoperative pyelitis and cystitis, and that the urine still shows pus and albumin, as well as casts. Furthermore, the patient now suffers with "dull pain along the path of the right ureter." Certainly a thorough urologic examination would seem in order, including pyelography. It is quite possible that the headaches may be of toxic nature and that the focus of infection may be a renal one, with possibly a stricture of the ureter. In such cases dilation of the stricture should relieve the pain along the ureter and may also help the headache and other symptoms. Other possible foci seem to have been adequately considered.

## HYPERTHYROIDISM

*To the Editor*—Twelve years ago I treated a patient, aged 42, for enlargement of the thyroid gland with mild tachycardia and slight nervousness. She was then in the menopausal state. The enlargement disappeared and she seemed improved and then discontinued medication. Three weeks ago she consulted me for tachycardia (150), nervous tremor, loss of weight and exophthalmos. She has no appreciable enlargement of the thyroid; in fact, I believe that the gland has almost disappeared. She is anemic, weighs 102½ pounds (46.5 Kg) and has 70 per cent hemoglobin. The urine is normal. My diagnosis is hyperthyroidism. The blood pressure on the first visit was 158/90, the second 152/70, the third 150/71, and the fourth 144/70. The pulse rate now is 108. The heart sounds are good, there are no murmurs and no irregularities. Digitalis, instead of raising the blood pressure, appears to be lowering it. I am prescribing along with digitalis some bromides and belladonna. The patient feels better but I do not know why she should show symptoms of hyperthyroidism with hardly any thyroid gland and why the blood pressure should fall steadily under medication that usually raises the blood pressure. It is possible that she was "kidding herself" in a false sense of good health during the intervening twelve years, but the thyroid is practically gone. I do not believe there is anything surgical in this case now. Have you any suggestions to make? I believe I have a case of toxic hyperthyroidism that is going to be very unsatisfactory to treat. Please omit name.

M D, New York.

**ANSWER.**—In exophthalmic goiter the average weight of the thyroid gland corresponds to the intensity of the hyperthyroidism. The ratio of the average basal rate to the average weight of the gland in grams is approximately one to one. While these averages are true, extreme variations take place.

In the majority of cases of exophthalmic goiter, enlargement of the thyroid gland is evident on palpation, if not on inspection. In a small percentage of cases the thyroid gland, even though enlarged, is not palpable. The portion of the thyroid gland remaining after thyroidectomy is palpable in the majority of cases of recurrence of hyperthyroidism. In a small percentage of cases it is not, and in rather rare instances the surgeon has difficulty in finding any remnant of the thyroid gland at the time of the secondary exploration. In most instances, even if there is only a small remnant, its removal satisfactorily drops the metabolic rate and relieves the patient.

## ERUPTIONS IN LUMBER WORKERS

*To the Editor*—In recent years since the virgin yellow pine timber has been exhausted in this section of the country, sawmills have been cutting second growth or sappy pine and, in order to prevent it mildewing or turning blue, various chemicals are being used as a dip for the lumber to preserve its natural color. October 24 I saw a patient who has come in contact daily with lumber so treated and his body gets damp with this solution. As a result his arms, legs and body have broken out in a raised eruption, from the size of a small shot to larger than a split buckshot, most of these places develop a pustule at the crest or peak. The solution being used in this case, I am told, is called Dowicide, and I believe it is made in New Orleans but I am not sure. I thought possibly that you might know what chemicals are in this solution and what may be the injurious element and the treatment for the condition. Please omit name.

M D, Mississippi.

**ANSWER.**—"Dowicides" represent a series of chlorinated phenolates. "Dowicide-H" is sodium tetrachlorophenoxide. These substances are believed to be made by the Dow Chemical Company of Midland, Mich., but in the South are distributed and serviced by the Chemical Treatment Company, Incorporated, in New Orleans. A large number of other substances, or have been, used as fungicides, such as mercury bichloride, potassium dichromate, creosotes, pine oil, arsenic compounds, sodium carbonate, calcium hypochlorite, carbonyl sulfide, ethylmercuric chloride and ethylmercuric phosphate. Many of these substances constitute distinct skin irritants and bring about a true occupational dermatitis when exposure is provided. Chapman, in "Chemical Control of Sap Stain in the South" (*Southern Lumberman* 149:82 [Dec. 15] 1934) says:

One difficulty which has been encountered with the chlorphenolate treatments when used in hand dipping vats has been the matter of irritation. A certain proportion of workmen who continually dip their hands in such solutions have been found to be susceptible to this irritation, which appears as a rash on the hands and forearms. Its occurrence is confined to mills using hand-dipping vats, workmen handling freshly dipped lumber at mills where automatic vats are used are very rarely troubled with it. For those who are bothered with this irritation, the prior application to the hands and forearms of ordinary engine oil or grease has been found very helpful. Experimental work with materials which could be added to the compound to prevent or greatly reduce such irritating effect is now under way, and it seems likely that further trouble from this source will soon be eliminated.

The skin lesion specified in this query undoubtedly is a result of exposure to Dowicide, although lack of personal cleanliness may have been a contributory factor, and a secondary entry of pyogenic bacteria or fungi may have complicated the original dermatitis venenata. Preferable to applications of "engine oil

or grease" is a protective coating made up of 75 per cent hydrous wool fat, 24.5 per cent olive oil and 0.5 per cent phenol. This preparation becomes rancid in time and containers require servicing. Although animal and vegetable fats are superior to mineral oils, white petrolatum containing 10 per cent camphor may be used. In the absence of sustained exposure, almost any bland treatment will eradicate this dermatitis, provided it is uncomplicated by a mycotic dermatitis. To soak with aluminum acetate or potassium permanganate is efficacious. Ten per cent zinc oxide in olive oil is useful, particularly after the acute state has passed. If complicated by the action of fungi, much more elaborate treatment may be required, including such medicaments as Whitfield's ointment, solutions of crystal violet dye or certain mercurials. Under any circumstances patients should avoid the use of harsh soaps, and particularly should eschew clean-up methods that include gasoline, benzene, naphtha or other hydrocarbons.

## VITAMIN B IN ANEMIA

*To the Editor*—My reading on the subject of the administration in true pernicious anemia of vitamin B in the form of yeast leaves me with the impression that this source of vitamin B requires being acted on by normal gastric juice. Is this impression correct? If so, such treatment would be impracticable in routine practice. If yeast is used for its vitamin B, what may be regarded as a necessary daily amount? Are tablets of from 6 to 7½ grains (0.4 to 0.5 Gm.) satisfactory? If Embo (General Mills, Inc.) is used for its vitamin B, what is the necessary daily amount to be effective, and may benefit be expected in the absence of a normal gastric juice, an achylia? Please omit name.

M D, California.

**ANSWER.**—The work of Castle and others has shown that yeast acted on by normal gastric juice is effective in bringing about a remission in pernicious anemia. Vitamin B, given in the form of yeast, is usually prescribed at the present time because of its general effect rather than for any specific effect on the lesions of pernicious anemia.

It may be given either as powder or as tablets, and it is customary to prescribe a level teaspoonful two or three times a day in the form of powder, or its equivalent in tablets. If Embo is given, the dosage is two or three teaspoonfuls each day.

The only benefit that could be expected would be from the general effect of giving these substances rather than from any specific effect on pernicious anemia. It is common practice to give both brewers' yeast and cod liver oil as adjuncts in the management of pernicious anemia. However, there are no scientific data to show that patients with pernicious anemia who are receiving adequate potent material (liver, stomach) get a better result when on a diet containing large amounts of these substances than when on just a well balanced diet.

## FOOD AND COLOR OF URINE

*To the Editor*—Can the ingestion of a considerable quantity of cooked beets or of tomato juice cause a red or pinkish color to the urine? I have consulted the large textbooks of Simon and of Webster on clinical laboratory methods, also the works of Todd and Sanford, of Russell Haden and of Kolmer and Boerner without finding any definite statement regarding this seemingly insignificant point. A woman brought me a specimen of urine from her little boy that was definitely pinkish, apparently from eating cooked beets. No chemical or microscopic evidence of blood was present and no albumin, and the child was perfectly well. Any references to the literature will be appreciated. M D, Nevada.

**ANSWER.**—The color of normal urine is yellowish or amber, but the tints even in health may vary considerably. The reaction also has an influence on the color, and highly acid urine frequently becomes darker on standing, because of the oxidation of chromogens. The urochrome that gives the yellow color to the urine is at least in part derived from the pigment chlorophyll present in green plants and consumed as foods. Traces of urobilin, present chiefly in the form of the chromogen urobilinogen, hematoporphyrin and uroerythrin (which gives the deep reddish tinge of urine in acute fevers) are also present.

Many foods and drugs will alter the color of the urine. The urine may become reddish after the eating of beets, and an intense yellow after the ingestion of carrots, owing to the coloring matter of these plants. A dark yellow or reddish brown may be due to rhubarb, cascara, senna, santonin or considerable salicylic acid. Red may be produced by antipyrine, acetanilid, sulfonmethane or sulfonethylmethane. A brownish black may be caused by resorcin, tannin, phenol (carbolic acid), guaiacal, thymol, phenyl salicylate, hematin or melannin. A greenish black is produced by phenyl salicylate or pyrogallol, and a blue or greenish blue by methylene blue. Phenylazo-2,6-diaminopyridine monohydrochloride, fuchsin and aminopyrine may cause a red orange. Bile pigments color the urine reddish

brown, brown or greenish and give to it a greenish yellow foam. Among foods, beets, carrots, tomatoes, rhubarb, and pigments of logwood, madder, bilberries, and fuchsin are the most common causes of abnormal coloration of the urine.

An excellent discussion of the color of the urine under normal and pathologic conditions may be found in "Urinary Analysis and Diagnosis," by Heitzmann, New York, William Wood & Co., 1934.

#### AZOOSPERMIA

*To the Editor:*—A man, aged 28, complains of sterility. Seven years ago he contracted gonorrhea. The discharge cleared under local treatment within a few weeks. He is small, 4 feet 5 inches (135 cm.) in height and weighs 128 pounds (58 Kg.). The ears, nose and throat are not abnormal. There is no goiter. The lungs are clear throughout. The heart and abdomen are normal. The reflexes are normal. The prostate is small and contains a few hard nodules. The left seminal vesicle is hard, tortuous and cordlike. The testicles are small and atrophied. The urethra shows a large stricture, admitting a No. 22 French sound with difficulty. Blood Wassermann tests and the Hinton test give negative results. The urine is normal except for one or two pus cells per high power field. The patient's wife has been thoroughly examined and is physically normal. They have been married four years and there have not been any pregnancies. The patient has received a long course of dilations up to 30 French and prostatic massage. A condom specimen on two occasions after this treatment has failed to show any spermatozoa, the seminal fluid being scanty, thin, and full of pus cells and lipid debris. A diagnosis of chronic vesiculitis, chronic prostatitis and urethral stricture, accompanied by aspermia, seems to prognosticate permanent and absolute sterility. However, the patient requests treatment with glandular extracts in an attempt to produce spermatogenesis. Is there at present any available glandular product of pituitary or orchic origin that will bring about spermatogenesis in atrophic testicles? Moreover, is it likely that any such therapy would render this man fertile or men who have chronic vesiculitis and probably occluded vasa deferentia? Please omit name.

M.D., New Hampshire.

*ANSWER.*—The cause of the azoospermia (not aspermia as mentioned in the query) may be due to the atrophic condition of the testicle or to occluded vasa or both. No mention is made in the query whether the original gonorrhea was accompanied by epididymitis and also whether the epididymides at present feel thickened, nodular and occluded. It would also be of interest to know whether the testicles were normal in appearance previous to the attack of gonorrhea. The mode of procedure at present would be as follows: The patient should be given 0.3 Gm. (5 grain) tablets of the anterior lobe of pituitary extract, one tablet four times a day for a week. The amount should be increased to two tablets four times a day for another week and again three tablets four times a day for another week and finally four tablets four times a day; that is, sixteen tablets a day, or 5 Gm. (80 grains) of the extract, which should be kept up for at least six months. This has frequently brought back the spermatogenic function of the testicles. If at the end of six months the condom still shows azoospermia, the condition may be due to occluded vasa and the differential diagnosis can be made by aspiration of the testicle after the method of Huhner (Aspiration of the Testicles in the Diagnosis and Prognosis of Sterility, *J. Urol.* 19:31 [Jan.] 1928). If no spermatozoa are found, the condition may be considered almost hopeless and certainly treatments should be discontinued. If, however, spermatozoa, even though few and inactive, are found, the operation of epididymovasostomy may be recommended, the patient being informed that the operation is only at times successful and that without operation there is absolutely no hope and then leaving it to him to decide.

#### DELAYED PUBERTY IN GIRL

*To the Editor:*—A Negress has not as yet begun to menstruate and also has not the least sign of a mammary gland development. These glands look just like the male glands. She feels healthy and is normal in weight and height for her age. The pubic hair is typically distributed. There is no hair on the face and no thyroid gland enlargement. The basal metabolic rate has not been determined. The blood pressure and heart rate are normal. Could you suggest a treatment that might be of some value in the case? She is 17 years of age. Please omit name.

M.D., North Carolina.

*ANSWER.*—It would be helpful in answering this query if one could know whether the basal metabolic rate, blood count and urine are normal. Assuming that they are, the girl should be given one of the gonadotropic preparations derived from the urine of pregnancy or from the placenta. Any of these is apt to be effective. This treatment should be continued, if necessary, for several months. She should also be given small doses of thyroid, beginning with 0.016 Gm. three times a day and increasing by 0.016 Gm. every fifth day until the dosage is reached that produces a slight tachycardia, tremor or nervousness.

#### INCOMPATIBILITY IN PRESCRIPTION

*To the Editor:*—On June 10, 1935, the following prescription of mine was compounded:

Codeine .....	gr. ½
Amidopyrine .....	gr. 5
Acetylsalicylic acid .....	gr. 10
Put in capsule No. 12. One P. R. N.	

The patient has taken these pills without any ill effect, but on August 28 she took one and within two hours became extremely ill with epigastric pains, persistent vomiting, headache, weakness and dizziness. Investigation showed that the material in the capsules had melted and had become yellowish. Will you inform me as to whether or not there can be any chemical reaction between the substances in the prescription with the formation of toxic material? Please omit name. M.D., Connecticut.

*ANSWER.*—In the presence of moisture there does occur a chemical change by reaction of amidopyrine and acetylsalicylic acid, the first step in which seems to be the liberation of acetic acid and a liquefaction of the ingredients. This might be accounted for by a splitting of acetylsalicylic acid into its two component radicals under the influence of moisture. There is no doubt that further changes occur, as the material on standing becomes yellowish and ultimately even dark brown. The exact nature of this ultimate product still remains to be determined. One can understand however that, even in the first stages of decomposition of the acetylsalicylic acid, both the acetic acid and the salicylic acid would be capable of producing irritation such as was noted. It may be of interest that the addition of starch to the powder before encapsulation is capable of preventing this decomposition.

#### USE OF TYPHOID VACCINE IN ARTHRITIS

*To the Editor:*—Relative to the article on page 1161 in *THE JOURNAL* of Oct. 5, 1935, regarding the treatment of arthritis, the statement was made that very good results have been obtained in the past from typhoid vaccine. Would you kindly advise whether it was Wright's vaccine that was used, the dosage, and the interval between doses?

G. M. McCURE, M.D., Fisher, Ill.

*ANSWER.*—The vaccine originally employed was an ordinary typhoid vaccine prepared by Wright's method. There is no objection, however, to using the so-called "Triple Typhoid Vaccine," each cubic centimeter of which contains *B. typhosus*, 1 billion organisms; *B. paratyphosus A*, 750 million organisms; *B. paratyphosus B*, 750 million organisms. The vaccine is killed by heat and preserved with 0.5 per cent trisecol.

When typhoid vaccine is to be used therapeutically, it is more convenient to dilute it 1 to 10 with salt solution. The first dose for adults is usually 25 million (though some recommend 50 million) injected directly into the vein. The chill and fever appear from thirty to forty-five minutes after the injection. In order to obtain good reactions, it is necessary to increase the dose after each injection. In fact, some writers recommend doubling the dose after each injection.

The interval between injections should be from three to six days.

The maximum benefit is usually obtained by from five to six injections. The patient should then have a rest of several weeks before the treatment is repeated.

#### USE OF ARTIFICIAL LIGHT IN VISUAL TESTS

*To the Editor:*—Please tell me why you advise testing visual acuity under artificial light, especially of such low illumination intensity as 7 to 10 foot candles.

HILMAR G. MARTIN, M.D., Milwaukee.

*ANSWER.*—In order to standardize as far as possible any subjective test, all possible variables must be of such known quantity and character as to permit of reproduction when desired. In the measurement of visual acuity, one of the greatest variables is the quantity of illumination. If daylight is utilized, the intensity of illumination may vary from only a few foot candles to as high as many thousand, depending on the time of day, the locality, the clearness of the sky and the atmosphere and innumerable other factors, all of which are beyond control. Consequently it is far better to use artificial illumination of known intensity, which can be reproduced at any time of the day or night in any locality as desired. It is well known that visual acuity increases only slightly with an increase in intensity of illumination beyond 9 foot candles, when the reflection factor of the background is around 80 per cent, as is the case with the test cards used in measuring visual acuity; on the other hand, the increase from zero to 9 foot candles is accompanied by an enormous increase in visual acuity (Seeing, by Luckiesh and Moss, 1931). Consequently, nothing is to be gained by using more than 10 foot candles except complication of illuminating apparatus and increased expense.

### INSERTION OF SUTURES BEFORE LACERATION IN CHILDBIRTH

*To the Editor:*—Does medical literature describe the placing of perineal sutures during the early part of the second stage of labor, such sutures to be tied after delivery in the event of there having been a laceration or to be withdrawn if no laceration occurs? I have been following this practice for a number of years in my obstetric cases with success in obtaining normal and exact approximation of the soft parts when lacerated during delivery.

A. B. BOWER, M.D., Armada, Mich.

**ANSWER.**—About fifty years ago, E. Laphorn Smith of Canada wrote about a method of putting stitches in the perineum before the baby was born, which stitches afterward were tied, bringing the torn structures together. On this recommendation it was done at the Cook County Hospital by several generations of interns but was found inadequate, because the muscle tears deeply at the sides, from the periosteum of the pubic rami and behind the rectum at the raphe which joins the two pillars of the levator ani, anterior to the coccyx.

DeLee has placed stitches in the perineum before doing episiotomy at the Chicago Lying-in Hospital for many years, but few have imitated this example, nor is there reference to this procedure in the literature.

### DIATHERMY AFTER FRACTURES

*To the Editor:*—1. Of what value is diathermy following fractures, especially subcapital fractures of the femur? 2. Does such treatment predispose to fibrous union? 3. If fibrous union should be occurring would it aid or diminish the process of bone deposition? 4. What is the optimum, maximum and minimum dosage of administration of diathermy for hip fractures (if it is indicated)? 5. Does the use or nonuse of diathermy alter the outlook in event the patient sues because of non-union? Please omit name.

M.D., Kansas.

**ANSWER.**—1. Although increasing blood supply might increase bone union, this is controversial.

2. No.

3. It would be of doubtful aid.

4. We do not believe that it is indicated, but when used the dose varies with the type of apparatus, size of electrodes, and bulk of the tissue treated.

5. No.

### NO RELATIONSHIP BETWEEN AMEBIC DYSENTERY AND DIABETES

*To the Editor:*—I have been consulted by a patient, a war veteran who saw service in France during the World War and who there contracted amebic dysentery, for which he was treated together with amebic abscesses of the liver, which resulted as a complication of the dysentery. Sometime after his war service he was found to have diabetes mellitus of a moderately severe grade, which has persisted up to the present time. 1. Is the amebic dysentery with the liver abscesses a causative factor in producing the diabetes? 2. Is there a possibility of direct invasion of the pancreas with amebas, resulting in pancreatic disease and diabetes? Please omit name.

M.D., Ohio.

**ANSWER.**—1. There is no evidence whatever that amebic dysentery complicated with liver abscess is a causative factor in producing diabetes.

2. There is no authentic report of invasion of the pancreas by *Endamoeba histolytica*. Such invasion is extremely unlikely and can be demonstrated only by authoritative postmortem examination.

In the case noted there would seem to be no reason for suspecting an etiologic relationship between amebiasis and the diabetes. Diabetes in amebiasis is apparently no more frequent than in other groups.

### ANGINA PECTORIS IN LOCOMOTIVE ENGINEER

*To the Editor:*—What can I do as a safety measure in a case of angina pectoris in a locomotive engineer? In order to be within the law one must be careful, yet one should be able to protect the public also.

M.D., Washington.

**ANSWER.**—No patient who has angina pectoris should ever, under any circumstances, drive a locomotive or engage in any occupation where his sudden incapacity would endanger himself or others. This applies equally well to any other possible source of sudden incapacity. His occupation demands his constant attention every moment. Even a slight attack of pain might divert his attention at a critical moment. A more serious hazard lies in the possibility of a coronary thrombosis while at work. Any person who has angina pectoris is much more liable to have a coronary thrombosis than one without such symptoms and in all probability will eventually die of such an attack. He should report his condition to the examining physician of the railroad at once.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

- ALASKA:** Juneau, Sept. 1. Sec., Dr. W. W. Council, Juneau.
- ALABAMA:** Montgomery, June 23-25. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.
- ARIZONA:** *Basic Science.* Tucson, June 16. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson. *Medical.* Phoenix, July 7-8. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.
- CALIFORNIA:** San Francisco, July 6-9, and Los Angeles, July 20-23. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.
- COLORADO:** Denver, July 7. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.
- CONNECTICUT:** *Medical (Regular).* Hartford, July 14-15. *Endorsement.* Hartford, July 28. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Medical (Homopathic).* Derby, July 14. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.
- DELAWARE:** July 14-16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.
- DISTRICT OF COLUMBIA:** Washington, July 13-14. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.
- FLORIDA:** Jacksonville, June 15-16. Sec., Dr. William M. Rowlett, P. O. Box 786, Tampa.
- HAWAII:** Honolulu, July 13-16. Sec., Dr. James A. Morgan, 48 Alexander Young Bldg., Honolulu.
- IDAHO:** Boise, Oct. 6. Commissioner of Law Enforcement, Hon. Emmitt Post, 205 State House, Boise.
- ILLINOIS:** Chicago, June 23-26. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.
- INDIANA:** Indianapolis, June 23-25. Sec., Board of Medical Registration and Examination, Dr. William R. Davidson, Room 5 State House Annex, Indianapolis.
- IOWA:** *Basic Science.* Des Moines, July 14. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.
- KANSAS:** Topeka, June 16-17. Sec., Board of Medical Registration and Examination, Dr. C. H. Ewing, 609 Broadway, Larned.
- MAINE:** Augusta, July 7-8. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.
- MARYLAND:** *Medical (Regular).* Baltimore, June 16. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Medical (Homopathic).* Baltimore, June 9-10. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.
- MASSACHUSETTS:** Boston, July 14-16. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.
- MINNESOTA:** Minneapolis, June 16-18. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.
- MISSISSIPPI:** Jackson, June 22-23. Sec., State Board of Health, Dr. Felix J. Underwood, Jackson.
- MONTANA:** Helena, Oct. 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.
- NEW HAMPSHIRE:** Concord, Sept. 10-11. Sec., Board of Registration in Medicine, Dr. Charles Duncan, State House, Concord.
- NEW JERSEY:** Trenton, June 16-17. Sec., Dr. Arthur W. Belting, 28 W. State St., Trenton.
- NEW MEXICO:** Santa Fe, Oct. 12-13. Sec., Dr. Le Grand Ward, Santa Fe.
- NEW YORK:** Albany, Buffalo, New York, and Syracuse, June 23-25. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 313 Education Bldg., Albany.
- NORTH CAROLINA:** Raleigh, June 15. Sec., Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.
- NORTH DAKOTA:** Grand Forks, July 7-10. Sec., Dr. G. M. Williamson, 4½ S. 3d St., Grand Forks.
- OHIO:** Columbus, June 16-19. Sec., State Medical Board, Dr. H. M. Platter, 21 W. Broad St., Columbus.
- OREGON:** *Medical.* Portland, June 16-18. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland. *Basic Science.* Corvallis, July 18. Sec., Mr. Charles D. Byrne, University of Oregon, Eugene.
- PENNSYLVANIA:** Philadelphia and Pittsburgh, July 7-11. Sec., Board of Medical Education and Licensure, Mr. Clarence E. Ackley, 400 Education Bldg., Harrisburg.
- PUERTO RICO:** San Juan, Sept. 1. Sec., Dr. O. Costa Mandry, Box 536, San Juan.
- RHODE ISLAND:** Providence, July 2-3. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.
- SOUTH CAROLINA:** Columbia, June 23. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.
- SOUTH DAKOTA:** Rapid City, July 21-22. Dir., Division of Medical Licensure, Dr. Park B. Jenkins, Pierre.
- TEXAS:** Austin, June 23-25. Sec., Dr. T. J. Crowe, 918-19-20 Mercantile Bldg., Dallas.
- UTAH:** Salt Lake City, July 10. Dir., Department of Registration, Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.
- VERMONT:** Burlington, June 24. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.
- VIRGINIA:** Richmond, June 18-20. Sec., Dr. J. W. Preston, 28½ Franklin Rd., Roanoke.
- WASHINGTON:** *Basic Science.* Seattle, July 9-10. *Medical.* Seattle, July 13-15. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.
- WEST VIRGINIA:** Bluefield, July 13. State Health Commissioner, Dr. Arthur E. McClue, Charleston.
- WISCONSIN:** Milwaukee, June 30-July 3. Sec., Dr. Robert E. Flynn, 401 Main St., La Crosse.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

**NATIONAL BOARD OF MEDICAL EXAMINERS.** *Parts I and II.* June 22-24 and Sept. 14-16. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

**AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY:** Written examination and review of case histories of Group B candidates will be held in various cities in the United States and Canada, Nov. 7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: New York, Sept. 26. All applications and case reports must be filed sixty days before date of examination. Address, 122 So. Michigan Ave., Chicago.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Cleveland, Jan. 9. Sec., Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: New York, Sept. 25-26. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Baltimore and Cincinnati in November. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 29-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Cleveland, Sept. 25-27. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester, Minn.

### California Reciprocity and Endorsement Report

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports 17 physicians licensed by reciprocity and 5 physicians licensed by endorsement from Jan. 2 through Jan. 30, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
College of Medical Evangelists.....	(1934)		Maryland
University of Colorado School of Medicine.....	(1933)		Colorado
Northwestern University Medical School.....	(1932), (1934)		Illinois
University of Illinois College of Medicine.....	(1934)		Illinois
University Medical College of Kansas City, Missouri.....	(1904)		Oregon
University of Nebraska College of Medicine.....	(1921)		N. Dakota.
(1905), (1926), (1934) Nebraska			
Columbia Univ. College of Physicians and Surgeons.....	(1926)		New York
New York University, University and Bellevue Hospital Medical College.....	(1906) Washington, (1924)		New York
University of Oklahoma School of Medicine.....	(1930)		Oklahoma
Meharry Medical College.....	(1933)		New York
University of Manitoba Faculty of Medicine.....	(1924)		N. Dakota
Queen's University Faculty of Medicine.....	(1924)		Michigan

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Leland Stanford Junior University School of Medicine.....	(1917)		U. S. Navy
University of Illinois College of Medicine.....	(1930)		U. S. Navy
Albany Medical College.....	(1929)		N. B. M. Ex.
Columbia Univ. Col. of Physicians and Surgeons.....	(1924)		N. B. M. Ex.
University of Oregon Medical School.....	(1931)		N. B. M. Ex.

### Wisconsin January Examination

Dr. Robert E. Flynn, secretary, Wisconsin State Board of Medical Examiners, reports the oral, written and practical examination held in Madison, Jan. 14-16, 1936. The examination covered 19 subjects and included 100 questions. An average of 75 per cent was required to pass. Fifteen candidates were examined, all of whom passed. Twenty-four physicians were licensed by reciprocity and 1 physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
College of Medical ..			1
Loyola University Sc ..			1
Northwestern Univs ..			2
Rush Medical College ..			2
Univ. of Minnesota 1 ..			3
University of Wisconsin Medical School.....	(1934, 4), (1935)		5
Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau ..	(1920)†		1

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Yale University School of Medicine.....	(1930)		Connecticut
Loyola University School of Medicine.....	(1931)		Illinois
Northwestern Univ. Medical School.....	(1930) Illinois, (1932)		Minnesota
Rush Medical College.....	(1928), (1934)		Illinois
University of Illinois College of Medicine.....	(1932), (1933)		Illinois
State University of Iowa College of Medicine (1922),	(1927)		Iowa

University of Wisconsin Medical School.....	(1931), (1931)		New York

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Northwestern University Medical School.....	(1916)		U. S. Navy

\* License has not been issued.

† Verification of graduation in process.

### Nevada Reciprocity Report

Dr. Edward E. Hamer, secretary, Nevada State Board of Medical Examiners, reports 2 physicians licensed by reciprocity after an oral examination held in Carson City, Feb. 3, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Loyola University School of Medicine.....	(1935)		California
Milwaukee Medical College.....	(1906)		Wisconsin

## Book Notices

**The Diagnosis and Treatment of Pulmonary Tuberculosis: A Handbook for Practitioners; A Text-Book for Students, Nurses and Social Workers.** By John B. Hawes, Jr., M.D., President of the Boston Tuberculosis Association, and Moses J. Stone, M.D., Assistant Professor, Diseases of the Chest, Boston University, School of Medicine. With a foreword by Richard C. Cabot, M.D. Cloth. Price, \$2.75. Pp. 215, with 44 illustrations. Philadelphia: Lea & Febiger, 1936.

Hawes and Stone have presented a brief historical sketch of tuberculosis in the human family, beginning with references on the Babylonian tablets and ending with the recent developments, such as chest surgery. Brief but adequate chapters on history taking and symptoms are included. In the discussion of the physical examination the minor and insignificant signs, which are often given much space, have been entirely omitted. This is greatly to the advantage of the reader, who will find only the important phases of the physical examination included. It is particularly significant that the authors included a chapter on the differential diagnosis of tuberculosis and other common diseases of the lungs and bronchi. In the chapter on pulmonary tuberculosis in childhood, attention is called to the fact that a positive tuberculin test is necessary for the diagnosis of the childhood type of tuberculosis. The tuberculin test, together with history of exposure and roentgen examination, is carefully considered. As regards treatment, many tuberculosis workers in this country will disagree with statements concerning the value of the preventorium for children with the childhood type of tuberculosis. The roentgen examination is stressed, but its substitution for the clinical examination of the patient is definitely condemned. The fact is emphasized that in the early development of pulmonary tuberculosis the x-rays may fail but that in most cases they give valuable information before one is able to elicit clinical signs and before symptoms are present. It is clear from the descriptions of shadows of tuberculosis and other diseases that one cannot determine the etiology of a pulmonary lesion with accuracy on a single roentgen examination. Emphasis is placed on the importance of repeated sputum examinations when tuberculosis is suspected and tubercle bacilli are not found in the first few examinations. Adequate space and conservative conclusions are drawn regarding the value of the blood sedimentation test and the leukocyte picture. In the chapter on treatment of pulmonary tuberculosis, attention is called to the work of Pratt and Minor, who like many others have accomplished excellent results by treating patients in the home; yet in homes where adequate facilities are not available such treatment should not be attempted. The recognized value of artificial pneumothorax in the treatment of pulmonary tuberculosis is pointed out. Other forms of collapse therapy, such as interruption of the phrenic nerve, intrapleural and extrapleural pneumolysis, and extrapleural thoracoplasty, are considered. In the chapter on heliotherapy, the authors have not expressed undue enthusiasm but look on this form of treatment as only one agent in an attempt to control tuberculous lesions. In no uncertain terms, Hawes and Stone advise against the use of BCG "until many disputed points in regard to it are cleared up and until we have far more definite knowledge as to its possible value and dangers than is at present available." This volume, although small, contains a great deal of valuable information and therefore deserves a place in the library of every physician.

**Modification of the Virulence of Tubercle Bacilli.** By N. Plum. Särtryck ur Skandinavisk veterinärtidskrift för bakteriologi, patologi samt kött- och mjölkhygien. Paper. Pp. 397-472. Uppsala: Almqvist & Wiksells Boktryckeri-A.-B., 1935.

This monograph (an English translation) details the work carried out in the State Veterinary Serum Laboratory during 1925 to 1930 and contains an extensive review of the literature, with a bibliography of 129 references. The survey forms a continuation of a previous monograph by the author on avian tuberculosis in mammals, in 1925-1926. Twelve charts on experimental data are included. The work has been painstaking in detail and the author admits many possibilities for error in results and interpretation. The problem was to make avian tubercle bacilli virulent for mammals and to make mammalian tubercle bacilli virulent for fowls. The cultural properties of

tubercle bacilli are reviewed and cases recorded in which mammalian tubercle bacilli were demonstrated in birds and avian tubercle bacilli in mammals. Mixtures of bovine and avian tubercle bacilli are inoculated through several generations of guinea-pigs, rabbits and hens, and it was found possible to separate the avian and bovine bacilli in the original mixture by this means, as fowls appear to be able to eliminate bovine bacilli from the mixtures while guinea-pigs eliminate the avian bacilli. These observations show that caution is necessary in judging the results, since the resistance of these experimental animals to the various tubercle bacilli is not absolute. Mammalian tubercle bacilli may live in fowls for a considerable length of time without giving rise to microscopic tuberculous changes, and avian bacilli may show some virulence for guinea-pigs, although this virulence will fail to appear in the next generation of pigs. The inoculation of material from tuberculous organs of fowls into guinea-pigs and rabbits showed that it was not practicable in this way to produce modification of the virulence of the bacilli employed. The inoculation of tuberculous organs of fowls into calves, rabbits, guinea-pigs and fowls showed a modified virulence in two of six series of experiments. The inoculation of tuberculous organs of cattle into guinea-pigs, rabbits and fowls showed a modification of the virulence in four of eleven series of experiments. A bovine culture injected intravenously into fowls and the organs injected into guinea-pigs, rabbits and hens in one experiment showed a modification of virulence of the bacilli. This monograph merits reading by all interested in tuberculosis and particularly by students engrossed in the experimental phases. It points out the difficulties encountered in solving so simple a problem as virulence of tubercle bacilli in the intricate disease tuberculosis. The author's concluding contention that it is actually possible with the technic given to modify the character of virulence in tubercle bacilli will be questioned by those conversant with experimental methods in tuberculosis, yet he is to be given credit for writing an excellent monograph on a difficult subject that still challenges undisputed proof. No doubt this problem will eventually succumb to the exacting weapons of the fundamental investigator now reenforced by the ever enlarging scope of new methods and stimulated by this monograph.

**Autistic Gestures: An Experimental Study in Symbolic Movement.** By Maurice H. Krout. Psychological Monographs. Edited by Joseph Peterson. Vol. XLVI, No. 4, Whole No. 208. Published for The American Psychological Association. Paper. Price, \$1.75. Pp. 126, with 10 illustrations. Princeton, N. J., and Albany, N. Y.: Psychological Review Company, 1935.

The present volume is an interesting monograph. The purpose is to determine whether spontaneous gesticulations or movements are significant as far as aiding in understanding the nature of mental mechanism is concerned. The author particularly wishes to find out whether autistic gestures or unconscious movements are sufficiently concrete so that they can be observed in a scientific manner, to find out whether the stimuli of these gestures can be determined through day-dream or reading responses, and whether there is any consistency of gesture in similar stimulus situations. The number of gestures was observed, classified and tabulated. The reliability of the observers in obtaining this material was also checked and correlated. The author concludes that autistic gestures cannot be interpreted even by individuals who conscientiously attempt to interpret them but require an "abstracted state" and special technics for their study; that the gestures are determinable through the stimuli with which they are associated in time and that there seems to be a reproduction of specific autistic gestures to a stimulus. These gestures probably originate in conflict situations of which they become symbolic, and they may be an escape mechanism in the presence of conflict and blockage. The author feels that further study of gestures will reveal information valuable for personality study. His conclusions seem fairly well justified from the material given. A study of this sort is highly specialized, lying between an experimental psychological point of view and the psychoanalytic. While one can criticize in some detail various weaknesses and see a tendency toward finding desired results where only speculation exists, in this monograph is

pointed out a means of personality study that might prove useful in the future. There is appended a list of 340 gestures that were observed. The material has little value except to the most advanced students of psychopathology.

**Atlas der klinischen Elektrokardiographie mit Anleitungen zur Differentialdiagnose.** Von Dr. Wilhelm Dressler, Assistent der "Herzstation" in Wien. Second edition. Paper. Price, 15 marks. Pp. 116, with 161 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1936.

The author has made a great improvement in this edition over the first. He has included a number of electrocardiograms, many of them with four leads, illustrating the changes seen in coronary occlusion and myocardial infarction. Thirty new illustrations have been added in the present edition to the 134 in the preceding one and a number of the old curves have been replaced by better ones. The illustrations are nicely reproduced, and the descriptions have been revised in many instances. As before, the electrocardiograms are placed on one page and the descriptions of the curves, the electrocardiographic diagnosis, and the pertinent clinical observations are printed on the opposite page. This permits the reader to arrive at his own interpretations independently if he desires this practice. This book is intended more for the cardiologist versed in the field of electrocardiography than for the beginner in this field. Many rare and involved arrhythmias are presented, which would be more confusing than beneficial to the general practitioner, the medical student or even the majority of internists. They are, however, well suited for the cardiologist wishing to become more expert in his electrocardiographic diagnosis. Naturally, there are a number of interpretations of records with which many authorities would disagree, the most obvious being figure 21. Furthermore, it is difficult to understand how an author so cognizant of the recent advances in electrocardiography can still persist in calling bundle branch block of the common type right bundle branch block. But these are minor criticisms and do not detract from the merits of the book. It is highly recommended for the cardiologist desiring advanced electrocardiography.

**Thirty-Third Annual Report, 1934-1935, of the Imperial Cancer Research Fund.** Under the Direction of the Royal College of Physicians of London and the Royal College of Surgeons of England. Paper. Pp. 35. London, 1935.

Dr. J. A. Murray, who has been director of the Imperial Cancer Research Fund since 1915, retired Oct. 1, 1935, and Dr. William Ewart Gye, formerly on the staff of the Imperial Cancer Research Fund (1913-1919), who has been working under the Medical Research Council for the past sixteen years, was appointed director. The report of the director cites the pessimism and confusion that prevailed in the medical profession in 1902 on the subject of cancer. Cancer in animals was practically unknown. The morbid anatomists regarded cancer as a cellular disease and, of the many hypotheses to explain its origin, only the Cohnheim theory of embryonic rests has survived as an explanation of certain rare malignant tumors. Hanau's first successful transplantation of a rat tumor to another rat and Morau's repetition of this experiment made little impression. Jensen's experiments made a more profound impression, as the Imperial Cancer Research Fund was just established and was just beginning to demonstrate that cancer was one of the few diseases common to man and all vertebrate animals. Bashford's studies of 10,000 cases critically analyzed revealed that in the accessible sites only 9 per cent had not been recognized clinically, while 7 per cent had been erroneously diagnosed as cancer. In the inaccessible sites the percentage of missed diagnoses was as high as 38, while only 9 per cent of cases had been erroneously diagnosed as cancer. Since cancer in inaccessible sites constitutes a large fraction of the total deaths, the recorded total cancer mortality must be considerably lower than the actual one. Improvements in methods of diagnosis and clinical recognition of cancer would tend to diminish the extent of missed diagnoses and increase the recorded mortality. If this argument is correct the increase in cancer mortality should fall mainly in the inaccessible group and less marked in the accessible. Investigation proved that the alleged increase fell mainly in the inaccessible group, more especially the stomach, while the skin and uterus showed no increase; in fact, the incidence of cancer of the uterus showed a decrease. The alarming statement that

cancer was appearing more frequently in the young was also disproved. These inquiries proved that cancer is not increasing at an alarming rate in civilized communities and that cancer is found when looked for among savage uncivilized people. Two aspects of the problem must be sharply distinguished: first, that which deals with the conversion of a normal cell into a malignant cell; second, that which deals with the properties of the malignant cell itself. Attention is again called to the existence of a group of filtering tumors caused by intracellular agents. The criticism that these are not true neoplasms seems to be wholly untenable. The belief is expressed that the knowledge of the disease gained in the last thirty years is more extensive than that of most other chronic diseases and has profoundly influenced its diagnosis and treatment.

**Principles of Hygiene. Part I: Principles of Constructive Hygiene. Part II: Principles of Defensive Hygiene.** By Thomas A. Storey, Ph.D., M.D., Director, School of Physical Education and Hygiene, Stanford University. Revised edition. Cloth. Price, \$3.50. Pp. 524, with 66 illustrations. Stanford University, California: Stanford University Press, 1935.

This revised edition of Dr. Storey's book is all that a textbook of hygiene for advanced students should be. It is not suitable for beginners but for the advanced student who needs to learn more of hygiene than just the principles useful in everyday living; it is a fine textbook, comprehensive without being heavy, scientific without being abstruse. It is well calculated to give the prospective sanitarian or public health official, or the teacher of health and hygiene, a practical working knowledge based on a sound comprehension of underlying principles. The first half of the book is devoted to principles of constructive hygiene; that is, a discussion of heredity, cellular physiology, nutrition, the structure and function of the body and its relation to the environment. In the second part the author discusses defensive hygiene; that is, the hereditary dangers, nutritional deficiencies, the abnormalities of growth and development and the unfavorable factors in the environment. A second volume, in preparation, is planned to take up the practice of hygiene based on the principles set forth in this book. For the undergraduate medical student or the student working toward a postgraduate degree in health and hygiene, or for the reference library of any college or university where hygiene is taught, this book can be recommended with confidence. It is well illustrated, clearly printed and adequately indexed. In this day of awakening interest in hygiene and public health on the part of his patients, the practicing physician might find it a useful addition to his library, not so much to impart knowledge as to correlate that which he possesses from the point of view of individual and group hygiene.

**A Textbook of Surgery.** Edited by Frederick Christopher, B.S., M.D., F.A.C.S., Associate Professor of Surgery at Northwestern University Medical School, Chicago. By American Authors. Cloth. Price, \$10. Pp. 1,608, with 1,349 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

This new surgical textbook is a large single volume and is the result of contributions from no less than 184 authors. The author selected in each instance is an authority in his field, a teacher, a master surgeon, a well known clinician or a research worker. The chapters, while brief and of necessity condensed, are informative and authoritative. The text differs from that of the older works in that it is not dogmatic. It is not calculated to create the impression in the student's mind that the information proffered is final; it reads rather like a report on a study in progress. This characteristic, coupled with short historical references and an appended bibliography, lifts it from the level of the all too dogmatic textbooks and places it in a close rapprochement with the current scientific medical literature. The student will receive from it the impression that no knowledge is final but that everything is subject to further investigation. The book reflects the best thought in American surgery. The uniformity in the care of presentation of subject matter, the excellence of its English and the appreciation of pedagogic requirements make this volume a valuable addition to our teaching armamentarium. All the chapters are adequately treated, but especially noteworthy are those on the relationship of bacteriology to surgery by Meleney, diseases of the thyroid gland and their management by Pemberton and

Haines, arthritis by Wagoner, the treatment of the autonomic nervous system by White, and the concise and exhaustive chapter on diseases of the liver and biliary system by Judd, Crisp and Waldron. While the book is written primarily for the student, the practicing surgeon will find it most useful for rapid orientation in any given field.

**Über die formale Genese des Lungenkrebses.** Von Kaj Lindberg. Arbeiten aus dem Pathologischen Institut der Universität Helsingfors (Finland), Neue Folge, Band IX. Heft 1-3. Gegründet von v. Prof. Dr. E. A. Hönén. Herausgegeben von Prof. Dr. Axel Wallgren. Paper. Pp. 400, with 560 illustrations. Jena: Gustav Fischer, 1935.

This monograph is based on a systematic study of the bronchial tree in primary carcinoma of the lung. In a number of cases a tendency to the development of many carcinomatous formations in the bronchial lining was established. A definite change in the bronchial epithelium in one or several places outside the main growth was demonstrated in more than a third of the cases studied. Such changes were found in the flat cell variety of carcinoma; it was not found in adenocarcinoma. The author emphasizes that he found only minute multiple carcinomas in addition to the large carcinoma and no other macroscopically recognizable primary growths with only one exception, in which case each lung was the seat of a primary carcinoma about as large as a fist. It seems as if the possibility must be considered that at least many of the small carcinomas developed long before death but that for some reason they grew slowly, perhaps on account of restraining influences originating from the large carcinoma. But there is also the possibility that the minute carcinomas, in some cases at least, developed shortly before death when the resistance of the body perhaps was broken down. Other phases of carcinoma of the lung, as, for instance, "precancerous" changes, spontaneous tumors of lungs in animals, efforts to produce tumors of the lungs experimentally, and earlier observations on changes in the bronchial epithelium in pulmonary carcinoma, are discussed also. The reports of the cases studied, with profuse illustrations, occupy no less than some 260 pages. There is a good bibliography. The monograph will be of great interest to all students of carcinoma of the lung.

**Introduction to Human Parasitology.** By Asa C. Chandler, M.S., Ph.D., Professor of Biology, Rice Institute, Houston, Texas. Fifth edition. Cloth. Price, \$5. Pp. 661, with 308 illustrations. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Limited, 1936.

Several features recommend the new edition of Chandler's Human Parasitology: it is as readable as former editions, especially for the nonparasitologist; it brings the subject to date, including in its pages progress in numerous fields during the last six years; it is useful as a ready reference for the physician in supplementing his knowledge concerning the numerous diseases ordinarily confined to the tropics but which appear with alarming frequency in temperate zones. The book is divided in three parts: protozoa, helminthology and arthropods. In the first part items of interest to the physician are syphilis and other spirochetal diseases, amebiasis and malaria; the second part is devoted to the worms, including especially tapeworms, hookworms and their allies, and trichinae; the last part presents methods by which mosquitoes, flies, fleas, ticks and the other arthropods may be recognized, and means for their destruction. The last chapter is devoted to fly maggots and myiasis, with several pages on the subject of myiasis of wounds. There are numerous illustrations scattered throughout the text, while at the end is a list of books and periodicals for the assistance of persons who desire to pursue the subject further.

**Doctor of the North Country.** By Earl Vinton McComb, M.D. With a preface by Logan Clendenning, M.D. Cloth. Price, \$2. Pp. 238. New York: Thomas Y. Crowell Company, 1936.

This is a sincere, unvarnished tale of the experiences of a doctor who has grown up with the lumbering country of the upper Michigan peninsula, has seen the lumber go and new times come, and all the way through has cared for and lived with his people. Brought up in the family of a physician, he early learned to admire and respect his father and, through him, the calling which he represented. The book has its laughs and its tears, and often they are close together, just as they are

in life. It has its grim aspects too, and in places the author indulges in mysticism, at which point he comes nearest to spoiling his book. However, as the introduction by Logan Clendening points out, doctor talk is the best talk there is, and this is good doctor talk. If a patient or two could pick it up from the waiting room table and read it while waiting for the doctor, it might help to dispel the state of the public mind to which Robert Morris referred when he characterized gratitude as one of the first symptoms of disease to disappear as convalescence sets in.

**Studies in the Psychology of Sex.** By Havelock Ellis. In Four Volumes. Cloth. Price, \$15, per set. Pp. 3,000. New York: Random House, 1936.

For many years these studies of the psychology of sex have been available only to physicians, sociologists and the legal profession. There is likely still to be some difference of opinion as to whether or not the time is ripe for the release of this material to general readers. However, the new publisher has purchased the plates of the original edition, has combined the original seven volumes into four handsome books in a nice wooden box, and makes the collection available at an exceedingly low price. The books have been enthusiastically greeted by reviewers in all the leading literary publications of the country. Certainly it is well to have these contributions of a great pioneer in this acceptable form. The volumes include such topics as sexual inversion, eonism, homosexuality, marriage and many similar subjects.

**Prognose und Therapie der Geisteskrankheiten.** Von Privatdozent Dr. Max Müller. Paper. Price, 7.20 marks. Pp. 164. Leipzig: Georg Thieme, 1936.

Müller summarizes the various types of therapy in the psychoses and puts into this little volume a tremendous amount of information. Interestingly, he compares the analytic method of treatment with other methods, calling the former an "uncovering" technic and the latter a "covering" technic, which is an excellent contrast. As a summary of the various methods of treatment, the work is well recommended.

**Essentials of Psychopathology.** By George W. Henry, Associate Professor of Psychiatry, Cornell University Medical School, New York. Cloth. Price, \$4. Pp. 312. Baltimore: William Wood & Company, 1935.

The author has written an elementary book concerned with general psychic mechanisms and their deviations from normal. He has done fairly adequately in his attempt to be fair to most of the important schools in psychiatry. There is a small amount of illustrated case material. Three hundred pages is hardly sufficient for an adequate summary of the field of psychopathology, so that this work serves simply as an appetizer to the beginning student in the field. It is recommended highly for this purpose.

**Neurose; Lebensnot; ärztliche Pflicht: Klinische Vorlesungen über Psychotherapie für Ärzte und Studierende.** Von Professor J. H. Schultz. Boards. Price, 4 marks. Pp. 125. Leipzig: Georg Thieme, 1936.

Under this queer title the author presents an elementary consideration of the neuroses as a result of certain needs within the patient and thus agrees with etiologic psychiatry. The work is intended more for general practitioners or the public and corresponds in content to the numerous works of a similar character published in England. It has no particular value to the specialist or to the general practitioner.

**Neurology and Psychiatry for Nurses.** By Frederick P. Moersch, B.S., M.D., Associate Professor of Neurology, The Mayo Foundation, Rochester, Minnesota. Boards. Price, \$1.85. Pp. 104, with 9 illustrations. Minneapolis, Minn.: Burgess Publishing Company, 1935.

The author has written a compact manual for nurses in which the essential data concerning nervous and mental diseases are included. There is an adequate reading list that indicates what supplementary work should be consulted. The material is given in a concise form, in fact is a brief outline, and as such may not be well suited for nurses. Its purpose as a means of review for examination could be stated as accomplished. This is not the best of the modern works that are available for nurses.

## Miscellany

### COUNTY MEDICAL SOCIETY LEADERSHIP IN PUBLIC HEALTH EDUCATION

WILLIAM J. CARRINGTON, M.D.

AND

ROBERT A. KILDUFFE, M.D.

ATLANTIC CITY, N. J.

The public today is health conscious as never before. Unfortunately much of the medical "information" disseminated to assuage public interest is grotesquely garbled and absurdly distorted. This is obvious to any one who tries to escape the bombastic bombardment of the radio, the billboard and the advertising sections of popular magazines, in which a molecule of medical fact becomes a mountain of unscientific balderdash authenticated (!) by innumerable "leading hospitals" and equally innumerable "physicians of prominence" possessing one attribute in common, anonymity.

That public ignorance and credulity should exist to a degree rendering such propaganda possible and profitable is not only regrettable but even, perhaps, astonishing. Doctors have long lamented the fact that otherwise intelligent people in quest of health sometimes, if not indeed, often, follow flickering fads over devious detours before returning, bruised and broken, to the straight and narrow path of reason.

But the same doctors have not always either admitted or lamented the fact that, to no small extent, the fault in this matter lies with physicians rather than with the laymen. Laymen possess a natural and lively thirst for medical knowledge. But physicians, wrapped in a mystic mantle of medieval reserve, have remained taciturn, have refused, except in a minor and often ineffective degree, to use the lay press and the radio, and to that extent have renounced leadership in public health education.

Physicians may well be annoyed at the preposterous misinformation that floods the air and crowds the printed page, and particularly at the subtle and often not so subtle intimation that it is all endorsed by the medical profession. But physicians who skip the page or turn the dial in bored disgust often fail to realize or admit that it is their own indifference or neglect which both cause and perpetuate this evil.

In the face of this indifference, within the past few decades numerous organizations have sprung up with the laudable and lofty purpose of educating the public in medical matters. With the aims of many of these, physicians have been in complete accord and have cooperated as fully, perhaps, as the insistent demands of private practice permit, for medicine is a jealous mistress. But nevertheless it is certain that the medical profession in general has not assumed the full leadership in the education of the public which is properly its place and its function.

To this end the Atlantic County Medical Society has recently departed somewhat from tradition in an endeavor to assume such leadership in its own community, and our purpose in this brief article is to describe what a small but well organized county society can do and is doing to tell its own public what they should know about medicine.

The origin of this action was largely accidental. On Sept. 24, 1935, a nurse was asked to plan a "town health meeting" for Atlantic City and received a publicity kit and guide from Mr. Prantz of the National Health Council. She was offered the services of Mr. Dennis J. Sullivan of the New Jersey State Department of Health. The meeting was to be a part of a nation-wide campaign of education on community health problems and was to be synchronized with hundreds of similar meetings, with nation-wide publicity and coast-to-coast radio programs. In spite of all the proffered lay help, the nurse

did not arrange a town health meeting. But, long after the nation-wide campaign, a minister came upon the unused plans and discussed them with a member of the chamber of commerce. By purest accident they fell into the hands of a physician, who brought them to the attention of the county medical society. The society eagerly seized on the idea and planned and consummated its highly successful town health meeting.

It is not our intent to criticize the National Health Council for failure to solicit the help of the county medical society in planning a campaign concerned with health; for, while this might seem a more proper method than to rely solely on lay individuals and lay organizations, it may well be that experience has taught the National Medical Council the difficulty of expecting effective leadership or even active participation in such matters from local medical societies.

This may seem, perhaps, an unwarranted and severe assumption. But the fact remains that there has been more than a modicum of medical indifference and neglect and, even when this has not been the case, the inability of physicians to express themselves and their views in a manner interesting to the public at large has more than once been commented on by those concerned with the dissemination of such material.

In any event, the town health meeting was held under the auspices of the Atlantic County Medical Society with short and pointed addresses by chosen members of the society on such subjects as Patent Medicines and Quackery, Periodic Health Examinations, Health Agencies, Socialized versus Organized Medicine, and other kindred, timely subjects.

Particular effort was devoted to making the addresses and the meeting interesting and concise, the speakers being enjoined to make their remarks pointed, striking and brief. To ensure this all addresses were edited by a committee chosen for the purpose and the time limit for each speaker was strictly enforced.

The town health meeting proved to be a decided success and produced a stirring revival of community interest in health matters, so much so that the society was prepared to rest on its oars, as it were, satisfied that something had been accomplished. But, fortunately, it was prevented from lapsing into self-satisfied lethargy by a comment from a newspaper editor. The press had been exceedingly generous with space given to the town meeting and very gracious in its favorable comments. But, in discussing the meeting afterward the editor commented: "This is all very well. It was a good idea and a good meeting. But the trouble with you medical men is that you start something, but you do not finish it! What comes next?"

What comes next? What should come next? The society suddenly realized that public interest, after all, is apt to be fitful and transient; that, like a human soul, it has a way of backsliding. It is not a single advertisement but its repetition and reiteration that bring returns. If the profession is to advertise public health and its importance, as it well may and should do, its efforts must not be spasmodic but, on the contrary, consistent and persistent if there are to be any lasting results.

So the Atlantic County Medical Society was confronted with the problem of how to maintain the public interest its town health meeting had aroused. It realized that numerous "health articles" are written by men of exceptional skill with years of experience and syndicated in nearly every newspaper in the country. But their articles lack specific community appeal. Moreover, the finances of a county medical society with only 114 members does not permit the employment of a physician not in practice with the requisite ability to act as a full time publicity agent. The society as a whole, therefore, undertook to sponsor, produce and carry on a series of articles on public matters to be printed once a week in the magazine section of the Atlantic City *Sunday Press* under the caption "Sponsored by the Atlantic County Medical Society."

Two difficulties at once presented themselves: What should be the character of the articles and how could it be ensured that they would have "news interest" and popular appeal?

The committee of four appointed to direct the project drew up, first of all, a tentative list of titles and, after first selecting individuals thought to be best fitted to discuss certain subjects, appealed for volunteers from the society at large to be given assignments from the remaining titles. The appeal was eminently successful.

The selection of subjects for the articles was in large degree governed by several factors:

(a) As a community project, it was thought desirable to lay some emphasis on its community aspects; for, without doubt, in any community there are many uninformed as to the degree and character of the facilities and agencies existing in the community in relation to public health. Various articles in the series were concerned, therefore, with the nature and character of the public health facilities of Atlantic City: its hospitals, convalescent homes and sanatoriums, its climatic and other aids in keeping well, and the opportunities for sane and healthful amusement and relaxation available to its residents: for who will deny that it is as important to keep well as to get well? Indeed, is not this the crux of preventive medicine?

(b) Admitting the often commented on inability of physicians to speak or write entertainingly of such matters, resulting, perhaps, from lack of practice, the committee reserved the right to reject, amend, edit and return to the author for rewriting when necessary all the papers submitted. Final acceptance or rejection as well as the order of publication was delegated to the editor of the *Press*.

(c) Recalling the old proverb that "few souls are saved after the first twenty minutes," an absolute maximum of 1,200 words was established and adhered to. In the endeavor to attract the attention of readers, particular care was given to the title. Thus "Care of the Aged" became "Life Can Begin at Sixty," "Pneumonia" became "The Captain of the Men of Death," and "The Healthy Child" was transformed into "Children of the Sun."

As an aid in arousing and maintaining community interest, and incidentally as an inducement to volunteers, each article appears over the signature of the author. By thus being neither anonymous nor by authors perhaps unknown to the majority of the community, they have a more personal community interest and possibly may thus be more generally read. But, in order to avoid any suggestion of personal advertising, as it were, certain precautions were made mandatory:

First, regardless of whatever titles the author may possess, such as, for example, F.A.C.S., F.A.C.P. or F.A.S.C.P., each article was signed simply as M.D., all other titles or positions, such as staff directorships, being omitted.

Second, all articles were rigidly deleted of personal pronouns and references to personal experiences.

Third, all polysyllabic technicalities were ruthlessly blue-penciled and every effort was made to secure articles not only accurate in detail but simple in expression and, whenever possible, with some intrinsic literary merit. Controversial subjects were tabu.

Finally, while a monotonous and parrot-like motif of "see your doctor" was studiously eliminated, the complete avoidance of any reference to self diagnosis or self treatment carried its own moral.

The Atlantic County Medical Society is using two other means of educating its public in health matters, the radio and accurate newspaper accounts of its scientific meetings. Both have proved quite satisfactory.

Twice a week for a period of fifteen minutes members of the society or distinguished medical visitors broadcast over station WPG. The announcer introduces the doctor by name

and states his subject but omits all titles, degrees or positions. The talks are plain, pointed and helpful, though aids in self diagnosis and self treatment are studiously avoided. The plan has been in operation for some time and has met the approval of lay listeners, the radio station and the profession.

For many years newspaper reporters sat wearily through the meetings of the medical society and wrote accounts for the press which contained an amazing amount of misinformation. For the past two years a member of the society with a nose for news has taken notes and after the meeting has had a press conference, so that the news accounts have been much more accurate, have contained but little misinformation and have been interesting to laymen as well as to the profession.

The public has responded well to the series of medical articles, to the radio talks and to the accounts of the medical meetings. It is true that the plan is young, but it is presented as an illustration of what can be done by any county society, large or small, in any county. It is admitted that to carry it out effectively is not easy; but the profession must recapture leadership in public health education. It can be done and done well if the desire to do it exists.

905 Pacific Avenue.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Optometry: Corporate Practice of Optometry Illegal in Kansas.**—The state, on relation of the attorney general, instituted original proceedings in quo warranto in the Supreme Court of Kansas against the defendant jewelry company, to determine whether it was engaged in the practice of optometry and, if so, to oust it from exercising any business as a corporation in the state. The corporation admitted that at the time of the filing of the petition, July 19, 1935, it employed a registered optometrist who made examinations and fitted glasses, and that all fees paid for services rendered by the optometrist were paid to the corporation which in turn paid the optometrist a specified salary. The corporation contended, however, that on the day on which the petition was filed against it, it "voluntarily" changed its method of doing business and rented to one Jacobs, a regularly licensed and practicing optometrist, space in its store and contracted with him to practice his profession in the rented space. As described by the Supreme Court, this contract provided:

The company agrees that in consideration of Jacobs maintaining the office and being in personal attendance during specified hours it will send to him for examination all customers for glasses coming to defendant's store requiring or requesting through its optical department such examination and will pay him for each examination \$2.75, settlement to be made on stated days. Jacobs agrees to purchase, maintain, and keep complete up-to-date equipment, and to make examinations of all customers on the basis of fees stipulated. Jacobs is also to have the right to carry on his own practice at said location and to collect and retain his fees therefor. Jacobs also agrees the company may by advertisement refer to the fact that an arrangement has been made with him to make such examinations, . . .

It would seem axiomatic, said the Supreme Court, where a statute requires a practitioner of optometry to be a person who is 21 years of age, of good moral character, and possessing specified educational qualifications, that no corporation may comply with such requirements. The court was convinced that the practice of optometry in Kansas is limited to individuals. The optometry act, continued the court, provides that any person shall be deemed a practitioner of optometry who shall display any advertisement offering in any manner to examine eyes, test eyes, or fit glasses with intent to induce people to avail themselves of the services advertised. The admission of the corporation that it advertised the free services of an optometrist convicted it of violating this provision of the act. The Supreme Court was not impressed by the argument on behalf

of the corporation that it changed its method of doing business on July 19, 1935, and that thereafter the optometrist was in control of the business and that it, the corporation, had no control over it. A similar arrangement was denounced, said the court, in *State v. Kindy Optical Company*, 216 Iowa 1157, 248 N. W. 332, in *Eisensmith v. Buhl Optical Company* (W. Va.), 178 S. E. 695, and in *Winslow v. Kansas State Board of Dental Examiners*, 115 Kan. 450, 223 P. 308. The contract of employment and the lease connected with it were devices, the court said, to avoid the provisions of the optometry practice act.

The Supreme Court therefore ordered that the corporation be ousted as a corporation exercising any claim, right or power to practice optometry, and that it be enjoined from doing any act constituting the practice of optometry. *State ex rel. Beck, Atty. Gen. v. Goldman Jewelry Co. (Kan.)*, 51 P. (2d) 995.

**Workmen's Compensation Acts: Relationship Between Silicosis and Disability; Expert Testimony.**—The sole question involved in this case was whether silicosis, which admittedly the claimant had, was a substantial factor in causing his disability, the exact nature of which the record does not disclose. The compensation commissioner dismissed the claim for compensation but, on appeal by the claimant, the superior court granted compensation. The employer thereupon appealed to the Supreme Court of Errors of Connecticut.

Three physicians testified before the commissioner. Two were of the opinion that silicosis was a substantial factor in causing the disability; the other, an expert in diseases of the lungs appearing for the employer, testified to the contrary. A finding or a conclusion, said the Supreme Court of Errors, cannot be held to be erroneous merely because it was based on the testimony or opinion of one witness in opposition to that of several others testifying to the contrary. A conclusion reached on comparison and examination of conflicting professional opinion, by reliance on one rather than another, can rarely be found erroneous in law in the absence of bad faith. The witness on whose testimony the commissioner relied in disallowing compensation gave as his reasons for his opinion that the silicosis was not a substantial factor in causing the disability the facts that the claimant was not suffering from shortness of breath, that the history given him by the claimant and his examination showed severe abdominal pain and tenderness from the beginning of the disability, and that the degree of silicosis, in his judgment, was late first or early second stage and not sufficient to cause disability. He testified that he did not have the benefit of a fluoroscopic examination in forming his opinion as had the two physicians who testified for the claimant. He was unable to determine the cause of the claimant's disability. We cannot say, said the court, that the commissioner could not have reasonably based his conclusion on the opinion advanced by this witness. In the conflict of opinion among the witnesses as to the cause of the claimant's disability, it was the province of the commissioner to determine the matter, and with his conclusion, the court said, neither the superior court nor the Supreme Court of Errors may interfere. The case was therefore remanded to the superior court with directions to dismiss the claimant's appeal. *Kulak v. Landers, Frary & Clark (Conn.)*, 181 A. 720.

## Society Proceedings

### COMING MEETINGS

- American Physiotherapy Association, Los Angeles, June 28-July 2. Miss Jefferson I. Brown, Tichenor Hospital School, Long Beach, Calif., Secretary.
- Conference of State and Provincial Health Authorities of North America, Vancouver, B. C., June 22-24. Dr. A. J. Chesley, State Department of Health, St. Paul, Minn., Secretary.
- Maine Medical Association, Rangleey, June 21-23. Miss Rebekah Gardner, 22 Arsenal St., Portland, Secretary.
- Medical Library Association, St. Paul, June 22-24. Miss Janet Do. 2 E. 103d St., New York, Secretary.
- Montana Medical Association of Billings, July 8-9. Dr. E. G. Balsom, 208½ North Broadway, Billings, Secretary.
- North Pacific Pediatric Society, Victoria, B. C., June 24-25. Dr. M. L. Bridgeman, 1020 S. W. Taylor St., Portland, Ore., Secretary.
- Pacific Northwest Medical Association, Portland, Ore., July 8-11. Dr. F. W. Countryman, 407 Riverside Avenue, Spokane, Wash., Executive Secretary.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

#### American Journal of Cancer, New York

26: 703-928 (April) 1936

- Multiple Primary Tumors of the Brain: Review of Literature and Report of Twenty-One Cases. C. B. Courville, Los Angeles.—p. 703.
- \*Malignant Melanomatosis. F. B. Plewes, Toronto.—p. 732.
- Thyroxine Production in Metastases from Carcinoma of Thyroid. R. B. Engelstad, Oslo, Norway.—p. 738.
- \*Experimental Production of Visceral Tumors with Hydrocarbons. F. W. Ilfeld, Boston.—p. 743.
- Production of Cancer by Hydrocarbons Other Than Those of Phenanthrene Type. A. A. Morton, C. F. Branch and D. B. Clapp, Boston.—p. 754.
- Relation Between Incidence of Mammary Cancer and Nature of Sexual Cycle in Various Strains of Mice: II. Relative Constancy of Characteristics of Sexual Cycle in These Strains. V. Suntzeff, E. L. Burns, Marian Moskop and L. Loeb, St. Louis.—p. 761.
- Precipitation Tests in Mice: Preliminary Report: I. Cancer; II. Comparative Study of Cancer Susceptible and Immune Mice. L. C. Strong and T. H. Werner, Bar Harbor, Maine.—p. 767.
- Effect of Shwartzman Reaction with Bacterial Filtrate on Transplantable Tumors in Animals. M. Jacobi, Brooklyn.—p. 770.
- Carcinoma of Tongue in a New-Born Child: Report of Case. L. W. Frank, C. D. Enfield and A. J. Miller, Louisville, Ky.—p. 775.
- Primary Adenocarcinoma of Liver in a Rooster. J. C. Norris, Atlanta, Ga.—p. 778.
- Adenocarcinoma of Sigmoid with Lymphatic Leukemia Blood Picture: Case. C. Reich, New York.—p. 781.
- Preparation of Dispersions of Carcinogenic Hydrocarbons in Serum: Note. E. Lorenz and H. B. Andervont, Boston.—p. 783.

**Malignant Melanomatosis.**—Plewes cites a case of malignant melanomatosis in which the first manifestations were those of sacro-iliac disease of rapid onset. The diagnosis was finally established by biopsy as secondary melanotic sarcoma. Search of numerous cutaneous moles, eyes, rectum and other possible sites for primary malignancy failed. There was widespread dissemination of malignant tumors, sometimes nonpigmented, which especially invaded the pelvic bones as well as the spine, ribs and skull, large veins and serous surfaces, and lymph nodes.

**Visceral Tumors Induced with Hydrocarbons.**—Ilfeld's experiments show that cancer can be induced in some of the visceral organs with certain carcinogenic hydrocarbons. He implanted cholesterol pellets containing 5 per cent of either 1:2:5:6-dibenzanthracene, methylcholanthrene or 1:2 benzpyrene into the kidney, spleen, liver, uterus, testicle, bone marrow, subperiosteum, stomach or brain of 244 experimental animals. Twelve renal tumors were caused by 1:2:5:6-dibenzanthracene cholesterol pellets and were epidermoid carcinomas. One renal tumor was transplanted through four generations of mice. The tumors seem to have originated from renal pelvic epithelium. There was a definite incubation period (average nine months) for the renal tumor; i. e., until it was large enough to be felt. The malignant change in mice and rats required a period of months. Examination of the fourteen kidneys containing dibenzanthracene pellets and having no tumor showed a moderate inflammatory reaction around the pellet with infiltration of polymorphonuclear leukocytes, lymphocytes and monocytes. In some slides renal pelvic epithelium partially or completely surrounded the pellet either in a single or in a stratified layer. This first reaction of the epithelium seemed to be a protective mechanism. The epithelial cells in most instances were supported by dense collagenous connective tissue. After coming into contact with the hydrocarbon, the epithelial cells became stratified and later assumed malignant characteristics, as shown by invasive downgrowths. The prolonged tumor incubation period might be considered as pointing to chronic irritation as the causative factor rather than chemical change. However, the evidence is not sufficient to

warrant a definite conclusion. The animals which had received the largest doses of dibenzanthracene developed tumors the earliest. While the amount of dibenzanthracene in the pellet varied from 0.08 to 0.6 mg., the amount of dibenzanthracene actually in contact with the cells was only that present on the surface of the pellet. Compared with the total amount of dibenzanthracene present in the pellet, this must have been a very small quantity. One fibrosarcoma was produced in the experiment. In this instance a pellet containing methylcholanthrene had been implanted in the spleen of a stock mouse. This tumor originated either from the connective tissue of the spleen or from the stroma of the pancreas, probably the former. In two tumors of the liver caused by dibenzanthracene the microscopic appearance is indefinite, because of postmortem changes; in one of these tumors it is consistent with the appearance of a primary liver cell carcinoma. A uterine tumor caused by dibenzanthracene is an epidermoid carcinoma originating from the endometrium. The results of inserting pellets into the other organs so far have been negative.

**Hypercholesterolemia of Pregnancy.**—Bartholomew and Kracke believe that the hypercholesterolemia of pregnancy is probably a normal physiologic response to meet the requirements of rapid cell growth in the fetus and prepare for lactation. An excessive degree of hypercholesterolemia of pregnancy is probably due to hyperpituitary or hypothyroid activity and

is further increased by a diet high in cholesterol-containing foods. Hypercholesteremia is probably the fundamental basis for the toxemias of pregnancy. It probably is responsible for nausea and vomiting of pregnancy, through an increased secretion into the bile until storage of this material can take place in the reticulo-endothelial system. Excessive storage in the liver in the first half of pregnancy is probably the cause of excessive fatty change in the periphery of the liver lobules with subsequent central necrosis in the inner zone of the lobules, which is so consistently found in fatal cases of pernicious vomiting of pregnancy. Excessive storage in the placental arteries with resulting vascular changes is the predisposing cause of infarction in the placenta. Thrombosis or rupture of a placental artery, occurring either spontaneously or produced by the trauma of fetal movements, is the exciting cause of acute infarction in the placenta. Acute or subacute infarction in the placenta results in autolysis of the affected tissue, with the liberation of peptone, guanidine and histamine as toxic split products of placental protein. The amount and location of the infarction, the degree of vessel obstruction and the rapidity of autolysis determine whether preeclampsia of mild or severe degree, eclampsia or premature detachment of the placenta will occur. If hypercholesteremia is the fundamental basis for the toxemias of pregnancy, it would seem that prophylaxis should be directed toward neutralizing the effect of excessive secretion of cholesterol into the intestinal tract through the bile and preventing excessive storage of cholesterol in the endothelial system by the administration of thyroid extract or iodine and restricting the use of fats and cholesterol-containing foods during pregnancy.

**Interstitial Irradiation of Cervix.**—Duncan suggests the following modification to Taussig's procedure (*Am. J. Obst. & Gynec.* 28:650 [Nov.] 1934; abstr. THE JOURNAL, Jan. 12, 1935, p. 152): 1. That the patient receive the initial roentgen and radium irradiation locally two months prior to operation and that the radium dose not exceed 6,000 mg. hours. 2. That the blood supply of the uterus be reduced by the resection of the uterine arteries, as reduction of blood supply decreases the spread of malignant tumors. 3. That sixteen 1-millicurie radon seeds be implanted; eight in the lower uterine segment, two in each broad ligament near the uterus and two in each sacro-uterine ligament. This would give a total radiation dose of 2,128 millicurie hours. 4. That all the retroperitoneal fat that is exposed be removed, for it may contain small lymph nodes.

### Congenital and Familial Cysts and Flocculi of Iris.

Cowan observed four cases of familial and congenital cysts of the retinal pigment layer of the iris, three of which he describes; in the fourth patient, now dead, a sister of one of the present patients, the anomaly was pronounced. The cysts were bilateral in each instance and consisted of pigmented masses and pouches filled with fluid, which projected from the posterior layers of the iris through the pupil and into the anterior chamber. Contraction of the pupil caused them to protrude farther into the anterior chamber. The cysts were capable of emptying and refilling. The ocular examinations were otherwise negative except that one patient had a divergent concomitant squint. Medical examination was negative in two of the cases; in the other there was a history of mental deficiency and chorea. The familial tendency of the condition in

these cases is sufficient verification that it is congenital in character, and that it is developmental and not the result of intra-uterine traumatism, as has been proposed. The theory of von Szily and Gallemaerts that it is due to a failure of closure of the annular sinus is logical, but the appearance of the stroma in these cases proves that this also is faulty in development and should be included in the malformation. The anomaly differs only in degree from that which is termed congenital ectropion uveae. There is also some justification for the traction theory of Vogt in the fibrous bands at the 2 o'clock position. But this was the only place in which, after careful observation of all six eyes, even a semblance of any adhesion was found between the pigmented epithelium and the stroma. It hardly lends weight to Vogt's hypothesis.

**Pneumoperitoneum in Intestinal Tuberculosis.**—Salkin declares that the treatment of secondary ulcerative intestinal tuberculosis is at the present time in the same stage as pulmonary tuberculosis was ten years ago. A hopeful view may now be taken despite the absence of a specific cure, as the various available modes of therapy may remove 80 per cent of the severe cases as complicating factors. Drugs and calcium are of secondary importance in themselves but highly useful with other agents; surgery has a very limited place; the diet may be individually selected. Ultraviolet irradiation benefits 40 per cent of moderate and 15 per cent of severe cases; vitamins benefit 67 per cent of moderate and 27 per cent of severe cases; pneumoperitoneum benefits all moderate and 80 per cent of severe cases. A new classification is offered, based on the roentgenologic extent of the lesion and the degree of symptomatic severity. The ulcerated intestine is influenced by two factors in its production of a state of spasm or irritability; namely, a local neuromuscular reaction and an extrinsic afferent-parasympathetic efferent reflex. It is possible that light and vitamins affect the threshold of irritability of the local factor, whereas pneumoperitoneum disturbs the proper function of the extrinsic reflex. Healing of ulcers takes place by a local and general increase of immunity further benefited by release of spasm and removal of distressing symptomatology. The existing views on prophylaxis and therapy must be modified and the presence of intestinal disease be regarded as an indication for active pulmonary collapse. The mode by which the air acts on the extrinsic nerves is problematic. The air acts by dampening the stimuli and thus may be likened to a buffer. The author concludes that air therapy acts by removing the extrinsic nerve reflex by a mechanical buffer action. The fact that ascites often causes an asymptomatic state in an ulcerated intestine shows further the mechanical action of a fluid body in the peritoneal cavity.

**Bilateral Pneumothorax in Treatment of Tuberculosis.**—Corsello and Bruckheimer do not advocate that all cases of advanced tuberculosis be subjected to bilateral pneumothorax irrespective of the patient's condition, but the measure should not be considered an agency of last resort. Cases that are obviously terminal or those in which the patient is dyspneic even while at rest because of extensive disease should not be subjected to the treatment. Those presenting caseopneumonic

lesions have responded most poorly to the treatment. Complications occurring during the course of treatment are the same as in unilateral pneumothorax: the most spectacular and distressing complication is that of a ruptured lung. While complications occur more frequently than in unilateral pneumothorax, this increased incidence is not great enough to contraindicate its use. Coulaud, among others, advises that patients with clinical tuberculous enteritis should not be treated by this method. However, the authors cannot wholly subscribe to this view. An involvement such as this undoubtedly adds to the hazards of the case, but recovery is possible in certain instances if satisfactory pulmonary collapse is obtained. In their patients who had intestinal tuberculosis and in whom the result was unsuccessful, they find that without exception all had unsatisfactory collapse of one or both sides. It is conceivable that with effective pneumothorax the result might have been different. One patient, who was gravely ill and had a severe intestinal involvement, made a gratifying recovery after both lungs were effectively collapsed. Of the authors' thirty-six patients having advanced pulmonary tuberculosis treated by bilateral simultaneous artificial pneumothorax, twenty-one are still alive, in eighteen of whom the disease is arrested or apparently arrested, and two are improved. One has suffered a recent reactivation of the disease after being well for two years, one year of which was after termination of treatment. Seven of those now living have returned to work. Nine others should be able to work in the near future.

**Surgical Treatment of Syringomyelia.**—Frazier and Rowe report two cases of syringomyelia in which surgical treatment resulted in improvement over periods of four and one half and two years, respectively. Fourteen additional cases from other clinics, whose period of postoperative observation was one year or more, have been analyzed. A review of the results in the sixteen cases shows that eight of the patients were sufficiently improved to return to their former occupations. Sex, age, the extent of the process or the preoperative clinical picture seemed to have little bearing on the operative results. Probably the duration of the disease and the technic employed may influence the end results to a certain extent. A review of the various technics employed suggests that: 1. A vertical chordotomy in the midline posteriorly or a few millimeters lateral to it on the side of the greatest cord damage (as evidenced by the clinical picture) is the most efficacious and the least dangerous approach to the syringomyelic cavity. 2. An attempt at establishing permanent drainage by the use of drainage material seems worth while. 3. If, after the initial drainage, the clinical course suggests a closure of the incision into the syringomyelic cavity, a second operation is indicated.

**Lumbar Ganglionectomy and Trunk Resection in Arthritis.**—Bothe points out that, from the results obtained to date, lumbar ganglionectomy is indicated only in a small per-

centage of patients with arthritis. It has not been used in osteo-arthritis or in hypertrophic or degenerative arthritis. The patient's general health should be maintained at the highest possible point at all times to obtain the best results. The post-operative restitution of use of the involved parts should be very slow and conservative. Heat and other physical therapeutic measures should be used with moderation as indicated. Orthopedic measures should be instituted to correct or overcome deformities. A borderline case is reported in which the clinical diagnosis was atrophic arthritis accompanied by or secondary to a vasomotor vascular disease of the extremities. The patient remained in the hospital for a period of five months, during which time all types of medical treatment had been instituted with no improvement. A bilateral lumbar ganglionectomy and trunk resection were performed. A periarterial sympathectomy was performed on the left common iliac artery. There was immediate improvement in the surface temperature and color of the involved parts. The postoperative routine of gradual introduction of exercise to the involved parts was instituted. The patient left the hospital five weeks after the operation, able to walk with crutches. Four months after operation she was using a cane and walked with very little difficulty. Her general condition had improved greatly, the swelling of the parts had disappeared and there was only a slight degree of pain produced on motion of the involved joints. After discarding the cane, only a limited amount of walking was permitted, but exercise was gradually increased. Twenty-two months after the operation, her general appearance was that of a normal healthy girl. She had been able to attend school regularly for one and one-half years and was able to walk an unlimited distance without any pain or disability. Two years after operation the patient stated that she continues to notice a gradual increase in her ability to use the lower extremity, and on palpation there was no evidence of any lowered surface temperature in the right leg. A cervicothoracic sympathectomy may also be performed when this condition exists in the upper extremities.

**Spontaneous Intracerebral Hemorrhage.**—Craig and Adson state that in two of their nine cases the etiology of spontaneous intracerebral hemorrhage was definitely the result of trauma. In another case the symptoms occurred two weeks after a period of strenuous exertion and emotional strain. In another case the hemorrhage was associated with rheumatic heart disease and endocarditis due to *Streptococcus viridans*, suggesting bacteriologic origin. In another case the etiology is uncertain, as the patient was found unconscious after having fallen from a wagon, and it was difficult to determine whether or not the unconsciousness preceded the fall. In two cases hemorrhage evidently occurred spontaneously when the patients (one a woman) were under emotional stress; there were no other etiologic factors. In the eighth case hemorrhage must have been traumatic in origin, although there was a history of injury twelve years previously, and in the ninth case hemorrhage occurred suddenly without apparent cause. After the clot had been evacuated and the cavity explored at operation there were no active bleeding points; in one case a pseudo-membrane surrounded the hemorrhage, and it was removed.

This would seem to disprove the theory that the bleeding was of arterial origin; it is the authors' opinion that the spontaneous intracerebral hemorrhage was of venous origin.

**Effect of Increased Oxygen Pressure on Epilepsy.**—Lennox and Behnke subjected to a high oxygen tension three young women who were having numerous petit mal attacks daily and with whom experience over a period of years had demonstrated that seizures invariably followed either the breathing of a low oxygen mixture or hyperpnea. On five occasions, one or more of the patients and the authors spent from three and one-half to five hours in a compression chamber under an absolute pressure of 4 atmospheres. Aside from the effect on seizures, they observed that, while under pressure, patients experienced about the same degree of mild intoxication as the observer. The only suggestive neurologic symptom was paresthesia in the distribution of an ulnar nerve in one patient. On days on which experiments were not carried out and which may be considered representative of the normal record of the patients, they had seizures at the average rate of 1.43 per hour; in the chamber the rate was 0.78 per hour. The excitement and discomfort of the experience might be expected to cause some increase in the number of seizures, but during the period of increased pressure spontaneous attacks were only 55 per cent as frequent as usual. Observations were made to determine the effect of varying pressures of oxygen on the length of time required to induce a seizure by this means. During the period of the test, patients while breathing oxygen were under an oxygen pressure nearly five times greater than the pressure while breathing air. Pressures of oxygen between zero and 3,000 mm. of mercury were obtainable. Twenty-eight hyperpnea experiments were made. The volume of air respired was calculated from the excursions of the bell of a Collins basal metabolism machine. In each of the patients, as the pressure of oxygen was increased, precipitation of a seizure by over-ventilation progressively required more time. The previous state of oxygen pressure seemed to exercise some influence. With a patient at a certain pressure, a greater volume of hyperpnea was necessary to induce a seizure when the patient was "coming down" from a higher pressure than when she was "going up." In one patient, when oxygen pressure was increased twenty-fold, the lung ventilation required to produce a seizure increased five-fold. Decreased oxygen tension tends to precipitate and increased oxygen tension tends to prevent petit mal seizures.

**Artificial Fever Therapy in Ocular Syphilis.**—Culler and Simpson subjected fifty-eight patients with syphilis who had an ocular complication of the disease to artificial fever therapy. In the fifty-eight cases diagnosis of the primary conditions was made in sixty-two eyes. In the 116 eyes associated secondary conditions due to syphilis were observed. The Kettering hypertherm was used for the induction and maintenance of fever. Approximately fifty hours of fever with temperatures above 105 F. in ten weekly sessions of five hours each was the rule. A course of thirty injections of bismarsen was given in conjunction with the fever treatments. Most of the patients with ocular syphilis who were chosen for this study had failed to respond to orthodox therapy. Of the eleven patients with interstitial keratitis, eight had experienced recurrences and ten had failed to respond to chemotherapy. The

duration of the disease and the tendency to recurrence appear to be distinctly lessened after the adequate fever therapy combined with chemotherapy. The response is most prompt in the cases in which an opaque central disk of plastic exudate exists. In ten cases of exudative uveitis prompt clinical improvement became apparent in every instance after the first one or two fever treatments. Nine patients recovered useful vision. Favorable response occurred in the lesions of fourteen patients with optic neuritis and neuroretinitis. All the patients recovered useful vision, although nine have residual pallor of the disk and some degree of contraction of the fields. Active neuritis of the optic tract appears to be arrested by fever therapy. Active choroiditis in seven patients subsided with fever therapy, with residual scars and defects of the fields. Good central vision resulted in all but one eye. In sixteen patients with atrophy of the optic nerve the visual acuity and visual fields remained practically unaltered after a course of fever therapy combined with chemotherapy. As in neurosyphilis, there is no parallelism between the clinical and the serologic response of syphilitic ocular disease to fever therapy combined with chemotherapy. The greatest field of usefulness for artificial fever therapy combined with specific therapy will ultimately be in its application to the early manifestations of syphilis, with a view to prevention of the often disastrous ocular complications.

**Intracranial Division of Auditory Nerve for Ménière's Disease.**—Since August 1931 McKenzie has carried out unilateral section of the vestibular portion of the auditory nerve on twelve patients. As a result of this experience he has concluded that it is possible to section the vestibular portion of the nerve with sufficient accuracy for clinical requirements. The caloric response is abolished and the attacks of vertigo cease, while at the same time the cochlear fibers function as before operation. The first patient was operated on in August 1931 but proved to be an unsatisfactory subject, as she had little or no hearing before operation. The second patient, however, had good hearing and satisfactorily proved the possibilities of this new procedure. One of the twelve patients died from a wound infection eleven days after operation. Apart from this unfortunate mishap, the results obtained have been very satisfactory. They are all extremely grateful for the relief which they have obtained, and although the postoperative period is short, varying from three years and five months to five months, one has no reason to anticipate a return of attacks. For a few weeks or months there has been a moderate degree of unsteadiness. This gradually disappears and patients become confident and cheerful and quite certain of their balance. Occasionally, on turning quickly in the dark, there is a slight tendency to fall to the involved side. Two of nine patients have had complete cessation of tinnitus, two were unchanged, and in five there has been a marked diminution. With two exceptions, all patients had an absence of the caloric response after operation. These have remained free from attacks, and this observation suggests that it is not necessary to cut all vestibular fibers to cure a patient. Of the twelve patients seven had such poor hearing on the involved side that it was of little importance to save the cochlear fibers. In each instance, however, the hearing which they did have was not impaired by the

operation and they have remained free of attacks. The remaining five patients had useful hearing, but two failures occurred in this group. One patient died and in the second case the cochlear fibers were unintentionally cut. The records of hearing before and after operation on the other three patients with good hearing illustrate the value of this operative procedure when it is desirable to save the cochlear fibers. The records show that hearing is being maintained on the involved side.

**Oxycephaly.**—Klein and Childe differentiate between true and delayed oxycephaly and what Greig terms "false oxycephaly." They cite two typical cases of true oxycephaly which occurred in a brother and sister. In spite of the obvious cranial deformity, the children had no complaints that would attract the attention of the examiner to the site of trouble. The diagnosis was established by the signs elicited on physical and roentgenographic examination. It has been suggested that oxycephaly may be hereditary, and the authors feel that their two cases tend to support this theory.

**Heterophile Pneumococcus Serum for Lobar Pneumonia.**—Noble and Kibler discuss 146 cases of lobar pneumonia treated at the Ancker Hospital between November 1934 and June 1935. Fifty patients were treated with heterophile pneumococcus serum and ninety-six received nonspecific therapy. Of the fifty patients treated with serum, nine died. Of the ninety-six patients treated nonspecifically, thirty-eight died. This appears to be a significant difference; however, the number of treated cases is small, and the control series is not beyond some criticism. The death rate in the nonserum cases is high, which is not unusual in certain epidemics of lobar pneumonia among the class of patients treated in a charity institution, such as the Ancker Hospital. Charts are presented showing the cases treated by serum and the nonspecifically treated cases arranged in age groups, analysis as to death rate in the four types of pneumococcal infection, the blood culture observations, and the time relationship between the onset of the pneumonia and the first dose of serum. The cases are analyzed as to the relationship of the time of onset to the time of hospitalization and a fourfold table for the forty-eight cases treated with heterophile serum and the seventy-two control subjects less than 60 years of age is given. The best that can be hoped for serum therapy in the treatment of lobar pneumonia is a decrease in mortality. In this series, it was felt that at least half of the patients were definitely improved clinically following the therapy, but there has been no statistically proved decrease in mortality. The probability integral of 0.12 is encouraging (Chi square), and, if this or better probability figures can be shown in other

similar series, the result would be considered encouraging. It is planned in the series now being studied to include determinations on the serum heterophile antibody in lobar pneumonia in treated and untreated cases.

**Recrudescence of Ovarian Function After Irradiation.**—Smith cites the cases of two women in whom periodic uterine bleeding occurred after truly large doses (a total of 6,000 and 5,400 mg. hours, respectively) of radium, and from whom functioning endometrium was obtained, indicating a return of ovarian activity. The first patient may have had ectopic ovarian tissue or a granulosa cell tumor, but this seems unlikely since she responded so well to a second treatment, remaining symptom-free thus far for three years and eight months. The diffuse enlargement of her uterus at the time of the second treatment, on the other hand, suggests the presence of a granulosa cell tumor. If the other patient had ectopic ovarian tissue, a return of function (amenorrhea for seven years) would have been expected sooner. The fact that her menstruation has been normal since reestablishment is on the whole against the presence of a granulosa cell tumor, although one such case has been encountered at the author's clinic. The finding of an endometrium showing the corpus luteum effect does not bear any weight for or against granulosa cell tumor, since secretory endometrium has been found in patients with these tumors when no other source of progesterin could be demonstrated. Hormone studies of recent years have cast doubt on the concept that ovaries are endowed at birth with their full quota of primordial follicles and suggest that follicles may be developed from the ovarian stroma in extra-uterine life. The fact that the second patient had a secretory endometrium after so long a period of amenorrhea may be interpreted as evidence for the evolution of a new crop of primordial follicles. It does not seem at all likely that any follicles which might have survived irradiation would have remained inactive for so long a time. Only one biopsy of the endometrium was made from the first patient and it did not show any corpus luteum effect; therefore no deductions can be drawn as to whether follicles may have developed anew.

**Modified Measles and Immunity.**—In February 1926 Townsend gave thirty-two boarding school students 9 cc. of convalescent whole blood at least eight days before the development of the rash. They experienced distinctly milder symptoms than their confrères who were not so treated. Replies have recently been received from the thirty-two individuals. In no case have any of them experienced a subsequent attack of measles. Nine individuals indicated that they had, to their knowledge, come into intimate contact with the disease, some of them several times. Five others stated that they had been present in communities while measles epidemics had been in progress but did not know of direct contact. The others made no observations about possible exposures, but most of them

were in school or college for about six of the ten years, and probably had ample opportunity for exposure. There is no evidence to date that the active immunity conferred by modified measles is any less satisfactory than that conferred by the unmodified disease.

**Abdominal Lymphoblastoma and Its Treatment by Irradiation.**—Desjardins and Watkins point out that many physicians have the impression that the manifestations of Hodgkin's disease and lymphosarcoma, especially the enlargement of lymph nodes, always begin in the neck and thence extend to the mediastinum, axilla, abdomen and groin. This is often true, but in some cases the disease first affects the abdominal, mediastinal or inguinal nodes and later spreads to other groups of nodes. Enlargement of retroperitoneal nodes, especially those around the celiac axis, as the earliest manifestation of the disease, is much more common than is generally realized. But even when the disease begins in the neck, axilla or mediastinum it tends to invade the retroperitoneal nodes sooner or later. The presence of Hodgkin's disease or lymphosarcoma in the retroperitoneal nodes usually is accompanied by more or less telltale symptoms. Pain is not a common complaint. Abdominal discomfort may be associated with nausea and irregularly with vomiting, or increasing constipation with

an increasing tendency to distention with gas, or both. The patient may complain of pain in the back on one or both sides, and the pain may extend to one or both hips and sometimes down one or both lower extremities. Sometimes pain in a lower extremity may be accompanied by edema attributable to enlargement of the iliac and inguinal nodes; when this occurs, it is usually in association with involvement of the retroperitoneal nodes. By themselves these symptoms are not conclusive; the most significant feature is their slow, gradual increase. Two symptoms, which are of great diagnostic importance when present but which are lacking in many cases, are fever and pruritus. Concerning the technic of irradiation for lymphoblastoma, some divergence of opinion still exists. Impressed by the immediate recession of lymphadenopathy when the affected regions are exposed to rays generated at 200 peak kilovolts, some physicians are not aware that equal or better results may be obtained with rays generated at 135 peak kilovolts and filtered through 4 or 6 mm. of aluminum, according to the situation of the nodes. Since the disease tends to extend from one group of nodes to another regardless of the technic of irradiation, it is wise to adopt a technic that can be repeated at intervals for an indefinite period. Maximal doses are to be avoided because of the danger of inducing cutaneous or other changes which may shortly prevent subsequent treatment. In lymphoblastoma and certain other neoplastic processes in which it is essential to include all the lymph nodes from the diaphragm down to and including the groin, this can be accomplished much more effectively by dividing the anterior aspect of the abdomen (from xiphoid cartilage to groin) into four fields with the navel as a center, and by dividing the posterior aspect into four additional and corresponding fields. The several beams of rays should be made to converge toward the median line, where most of the nodes are situated. Thus, not only are the abdomen and its contents more uniformly irradiated, but the effect of many converging beams of rays on the lymphoblastomatous process and its clinical manifestations is much greater than when only one anterior and one posterior field are exposed. In women who still menstruate irradiation of the pelvis should be avoided, unless marked lymphoblastomatous infiltration of the iliac nodes or of some of the pelvic structures should force the physician to disregard menstrual function. Not only the obviously affected regions but all the more important groups of lymph nodes should be systematically irradiated. The treatment should be repeated at regular intervals of three or four weeks (unless pronounced leukopenia should prevent) until the lymphadenopathy has disappeared or until maximal regression of the enlarged nodes has been obtained. Even after apparently complete regression of the nodes, it is wise to give at least one more course of treatment. Only thus may prolonged arrest of the disease and improvement in the condition of many patients be expected.

**Some Biochemical Factors of Heart Failure.**—In addition to the chemical studies of human heart muscle, Herrmann and his associates have carried out various experimental procedures on several series of mammalian hearts and then analyzed the muscle. The total creatine content has been the object of most of their chemical analyses. The clinical experimental biochemical facts seem to point the way toward the ultimate solution of the problem of myocardial weakness or heart failure. The most logical deduction from the mass of data concerning the physical mechanism of heart failure and ten years of clinical and experimental work led Harrison to the conclusion that the chief factor in heart failure is anoxemia, an actual reduction of the diffusion of oxygen into the heart muscle cell. The thickened heart muscle cell of compensatory hypertrophy in itself impedes oxygen diffusion; the arteriolar and arterial sclerosis add some further barrier to maximal and adequate oxygenation. These factors alone lead to an anoxemia of heart muscle, and this in turn may initiate a train of chemical changes that further impair the functional capacity of the heart. The effect of inadequate cellular oxygen supply on cellular metabolism is that the synthesis of muscle glycogen is interfered with, the lactic acid that results from glycogen breakdown during contraction is not completely resynthesized and accumulates, and an acidosis results as the organic acid uses up the buffers of the blood. The phosphocreatine breakdown to creatine and phosphate liberates the energy of contrac-

tion even under anaerobic conditions, but the fairly constant relationship of aerobiosis is lost and the phosphocreatine disappears more rapidly than the glycogen, and the ratio falls. The increasing  $p_{H}$  likewise speeds up the velocity of phosphocreatine hydrolysis, and this may well hold the concentration at a low level and interfere with resynthesis and thus contribute to myocardial weakness. The potassium ion of the creatine phosphoric acid secondary salt may be lost under the conditions of anoxemia. The resynthesis of the phosphocreatine after the contraction apparently depends on the energy liberated by the delayed lactic acid formation. Some lactic acid is oxidized to carbon dioxide and water, but in anoxemia there is a rapid accumulation of lactic acid in the tissues and the blood, and the mammalian heart does not tolerate any concentration above 0.07 Gm. per hundred cubic centimeters without showing signs of exhaustion. The analysis of such exhausted hearts shows striking losses in total creatine content. It is therefore reasonable, in view of the facts known about the relation of phosphocreatine to cardiac energy, to consider heart failure a matter of disturbed glycogen-phosphocreatine metabolism.

**Dentin Desensitization.**—The painful reaction of dentin to denturing procedures led Hartman to believe that it was probably due to the presence of lipoids in this tissue. Working on this assumption, he prepared a solution containing the lipoid solvents, alcohol and ether, and thymol, a substance soluble in lipoids. The formula (one and one-fourth parts of thymol, one part of 95 per cent ethyl alcohol and two parts of sulfuric ether) has been found effective in relieving pain during operations on dentin. The solution should be kept in a tightly corked brown glass bottle. Half an ounce of the solution is sufficient for 200 applications. Only cork or tin lined stoppers should be used. It is applied topically. The cavity is packed with dry cotton and a pellet of cotton is moistened in the liquid and held in contact with the cotton in the cavity for one minute in children and one and one-half minutes in adults. Both pellets are removed. Warm air is used to leave a film of thymol on the surface of the cavity. If applied over caries, a second application may be necessary after the caries has been removed.

\*Diphtherial Infection of Scirrhus Carcinoma. W. Marshall, C. D. Neidhold and V. F. Marshall, Appleton, Wis.—p. 230.

**Diphtherial Infection of Scirrhus Carcinoma.**—Marshall and his associates report the case of a woman, aged 57, who noticed that the nipple of the left breast began to harden about one and a half years before. She stated that the area of the breast just superior to this nipple "turned in" and formed a "pimple" which did not open for a period of three or four months. It finally opened during January 1934. Since that time it had been draining slightly. The discharge was serous in type. There never had been any pain connected with the lesion. However, it did itch. A smear was taken from the sinus and a culture was made. The examination suggested a "diphtheroid" type of organism. A guinea-pig was inoculated with a culture and died within forty-eight hours. The necropsy revealed hemorrhages into the adrenals. The technician obtained a pure culture from a Loeffler's slant. These bacteria were gram-positive and were beaded and exhibited clubbed ends. Furthermore, they exhibited the peculiar palisade arrangement or "hen's tracks." The necropsy observations of the injected guinea-pig were typically those caused by the Klebs-Loeffler bacilli. Several days later, cultures were taken from the patient's nose and throat. They did not exhibit this type of organism. Repeated cultures of the nose and throat gave the same results. The intracutaneous tuberculin test was positive within twenty-four hours. The control on the opposite arm was negative. The Schick test was negative, as was the control. The diagnosis was scirrhus carcinoma of the breast with secondary infection. The entire left breast was removed by the Willy-Meyer technic. It was atrophic and had very little glandular tissue remaining. There were some lipid strands in the sclerosed tissue of the breast. The skin was heavily infiltrated with scirrhus carcinoma, and under examination exhibited the typical "pigskin" appearance. The axillary glands contained metastatic tumor growths, and cancerous proliferations were noted in the axillary regions and involved the underlying musculature and blood vessels. The pathologic diagnosis was scirrhus carcinoma of the breast with metastases to the lymph glands. As the patient improved from the operation, three doses of roentgen therapy, totaling 1,300 roentgen units, were given the left chest and neck regions. Some days later the area on the left breast, which was without skin, was covered with skin transplants (Thiersch grafts). These grafts grew well. In the course of about two weeks the patient was discharged from the hospital. However, a few months later, she began to experience symptoms which pointed to metastases to the brain and the skeletal system and she died within a period of six months. The patient may have been a carrier of the Klebs-Loeffler organism or she may have inoculated her breast with the pathogen.

**Protection from Gamma Radiation Afforded by Building Materials.**—Kaye and his co-workers deal with the part which building materials can play in providing protection against gamma rays for workers and others in the vicinity of radium bombs. Transmission measurements were conducted with narrow beams and with wider beams under everyday conditions, in which the influence of scattered radiation is almost always pronounced. The materials tested were full-scale walls of brickwork from 4 to 23 inches thick and solid steel doors up to 3½ inches thick, as well as smaller specimens of lead, iron, aluminum, brick, coke breeze and concrete of various thicknesses. Up to several grams of radium was used as a source of radiation, and the transmission measurements were made by means of thick air-walled ionization chambers, so as to simulate the conditions relating to deep seated tissue. It is customary to regard the absorption of gamma rays by different materials as proportional to their densities, but the present results show that, while the relationship is sufficiently exact for the lighter elements, it requires correction when comparing light and heavy elements, owing to photo-electric absorption in the latter. Protective values are commonly quoted in terms of lead, but when these are translated into terms of building materials, by the aid of the density law, the thicknesses so derived should be increased by up to about 50 per cent for the radium beam from a typical present-day bomb.

**Relation of Parathyroids to Urinary Lithiasis.**—Among 340 patients with urinary lithiasis, Barney and Mintz discovered twelve cases, 4.16 per cent, of hyperparathyroidism proved by operation. Several other cases in which the observations were suggestive may be so affected. They believe that the studies being made of parathyroid disease in its relation to urinary stone may lead eventually to the solution of a great problem. The study of the subject of urinary lithiasis, whether due to hyperparathyroidism or to other causes, is not to be considered ended with the removal of the parathyroid tumor, of the stone or of both. There should be frequent follow up of the patients. A careful dietary regimen should be laid out; blood and urine chemistry should be frequently investigated; the urine should be kept strongly acid, preferably with ammonium chloride, and roentgenograms of the urinary tract should be taken from time to time. Only then will it be possible to put these investigations on a foundation of certainty. While hyperparathyroidism is responsible for between 4 and 5 per cent of all cases of urinary stone, the proportion of stones in the presence of this disease may be almost 70 per cent. Patients may show patho-

logic changes of bone and the urinary tract in about 38 per cent of cases of hyperparathyroidism. This disease does not seem to be a factor in the production of bilateral lithiasis. The symptoms and signs of urinary lithiasis in parathyroid tumors do not differ from those due to other causes.

**Cod Liver Oil Treatment of Wounds.**—Tennent has used cod liver oil in the treatment of a varied series of wounds. The method is comparatively painless; it is efficient, results in a great reduction in the number of dressings required, and is simple and cheap. The one disadvantage is the characteristic odor, but in none of the author's cases has the odor been an insuperable difficulty. He briefly refers to three of his most striking cases: a severe burn, an accidentally opened knee joint and a wound from a charge of shot at close range in the right buttock. Treatment with cod liver oil has given most gratifying results, confirming those of Steel.

**Bacteriophage in Treatment of Cholera.**—Of 1,369 patients with cholera admitted during the year ended July 1935, Pasricha and his associates treated 684 with cholera-phage, while 685 received the usual hospital treatment. The selection was made by taking alternate admissions into the wards, irrespective of age, severity and general condition of the patient. Both series received the usual hospital routine treatment for cholera, and the phage-treated patients received in addition cholera-phage in doses of 2 cc. every four hours. The only medication given orally was in the form of divided doses of mercury bichloride. Every patient was examined bacteriologically on the day of admission. Later, examinations were made at least once in every twenty-four hours, up to the complete dis-

appearance of symptoms, and when possible a certain number of cases were followed up after discharge from the hospital. Special efforts were made to examine repeatedly cases clinically positive but bacteriologically negative. Choleraphage used for treatment was prepared on freshly isolated agglutinable strains and constantly "refreshed" on recently isolated vibrios. Freshly isolated potent phages were frequently added to the "seed phages" and every effort was made to ensure the presence of a larger number of types of choleraphage in each brew. The only criterion of the results of treatment employed has been recovery or death. The gross mortality is less, though not statistically significant, in the cases treated with choleraphage. The difference in the mortality rates between the series is more marked during the period when the cases treated with choleraphage were in a separate ward. In cases of clinical cholera in which vibrios were isolated, bacteriophage is of definite therapeutic value. Of the total number of 398 patients with cholera passing vibrios in the series treated with the choleraphage, agglutinable vibrios were found in 337 cases, or approximately 85 per cent. The mortality in this group was 8.3 per cent. Of the 443 patients in the series not treated with the choleraphage, 369, or 83 per cent, were found to pass agglutinable vibrios. The mortality in this group was 20.6 per cent. The results in this group are statistically significant. Choleraphage gave unfavorable results in the cases in which, in spite of repeated search, only inagglutinable vibrios were found. The mortality in this group (sixty-one cases) was 8.2 per cent, as compared with 4.7 per cent in the control series (seventy-four cases). No satisfactory explanation can be advanced for this failure. However, the choleraphage used in the experiment had been propagated only on agglutinable vibrios. The effect of bacteriophage prepared on inagglutinable vibrios, or a therapeutic bacteriophage prepared on both agglutinable and inagglutinable vibrios of a particular epidemic, still remains to be determined. There is an appreciable difference in the treated and control series of cases. The patients are less toxic, there is less dehydration, and fewer injections of sodium chloride solution are required in the treated series than in the controls; also the patients are discharged sooner, secrete vibrios for a smaller number of days and in general have a clinically milder course. Uremia and other complications are often averted, or, if they supervene, are milder in the treated series.

- The Commonwealth of Medicine: Yesterday W. R. Fearon—p. 49.  
\*Generalized Osteitis Fibrosa Cystica W. J. E. Jessop—p. 59.

**Generalized Cystic Fibrotic Osteitis.**—Jessop says that in generalized cystic fibrotic osteitis there is hyperactivity of the parathyroids associated with hyperplasia and resulting in the production of excessive secretion. Under the influence of this excess parathyroid hormone calcium salts are mobilized from the bones, which consequently suffer loss in strength as shown by deformity and spontaneous fracture. There is lack of density in the shadows with localized cyst formation. The bone is replaced by fibrous tissue. There is considerable osteoporosis, and the arrangement of the osteoclasts and osteoblasts affords evidence of absorption and new bone formation. These two processes often proceed in an irregular manner and the new bone rarely shows a normal arrangement in haversian systems. The amount of calcium in the blood increases and there is increased excretion of calcium salts, especially in the urine. The necessity for maintaining osmotic equilibrium in the kidney leads to polyuria, which is accompanied by thirst. The effort on the part of the organism to bring about a com-

pensatory increase in new bone formation leads to an increase of the concentration of phosphatase in the plasma. The concentration of calcium in the plasma is known to control the tone and excitability of muscle. In parathyroid tetany the diminished blood calcium is accompanied by increased muscle tone and muscular hyperexcitability, and a return to normal follows intravenous injection of calcium chloride in sufficient quantity to restore the blood calcium to normal level. Similarly, continued injection of parathyroid extract produces an increase in blood calcium and a state of diminished tone and excitability in muscle. The increased blood calcium in cases of parathyroid tumor (generalized fibrotic osteitis) is frequently accompanied by like muscular changes, which are corrected by the removal of the (parathyroid) tumor. Certain other clinical features are of interest. The disease is most common in women between the ages of 30 and 60 years and is often accompanied by weakness and loss of weight and a hypochromic anemia. During the course of the disease there is often much pain and tenderness in the bones or joints. Pronounced changes are found in the skull, which becomes enlarged, with prominence of the forehead. The total number of cases at present recorded is variously estimated at between fifty and 100, but the higher figure probably includes many in which the parathyroid enlargement was found post mortem and others in which slightly enlarged or normal parathyroids were removed from atypical cases.

**Iron in Nutrition.**—Widdowson and McCance assessed the total and "available" iron intakes of sixty-three men and sixty-three women of the English middle class, whose ages ranged from 18 to 90 years and who were living on freely chosen diets with no restrictions due to income or other cause. Their occupations were sedentary or moderately active; a few manual laborers were included. The mean intake of total iron for the men was 168 mg. a day; however, 37 per cent of the men were consuming a diet containing less than 15 mg. a day, and the minimum (78 mg.) was little more than half. The average intake of total iron for the women was 11.4 mg. a day, and 30 per cent of the women were taking less than 10 mg. of iron daily. The chief source of iron in the English diet is meat. The available iron intake for men had a mean value of 10.8 mg. a day. The corresponding figure for women was 7.9 mg. This higher percentage of total iron taken in an available form by the women is due to their lower intake of meat, which contains much total iron but relatively little available iron. Hemoglobin determinations were made on forty-two of the men and twenty-nine of the women. Mean values of 102 per cent for men and 93 per cent for women were obtained. These results must be considered to be within the normal range (Price-Jones, 1931). No correlation could be found among the women between the total or available iron intake and the percentage of hemoglobin in the blood. For the men the correlation was not significant for the total iron but was

just significant for the available iron. This does not prove that the intake of iron is not a factor in regulating the level of hemoglobin in the blood. It merely shows that under these conditions other factors involving absorption, excretion and menstrual loss predominate. The lower percentage of hemoglobin in women's blood must be due either to some physiologic cause or to the fact that their iron intake is insufficient for their requirements. A dietary cause should be sought for the lower hemoglobin levels in women. The effect of large doses of iron (100 mg. of iron a day as ferrous sulfate or ferric ammonium citrate) on normal hemoglobin levels scarcely altered the hemoglobin percentages of men but has increased the values for women by from 4 to 17 per cent, and a mean rise of more than 10 per cent has been observed.

**Antistreptolysin Titers of Serum in Health and Infection.**—Stuart compared streptolysin production by twenty-seven strains of hemolytic streptococci grown in a special buffered dextrose serum-free broth and observed a marked variation. The antistreptolysin titers in healthy individuals and in others at the commencement of illness showed a pronounced variation. Throat infections with *Streptococcus haemolyticus* usually produced a rise in the level of circulating antistreptolysin in the patients' blood, and this could be considered diagnostically significant. Throat infections with hemolytic streptococci showed rather more rapid production and higher titers of antistreptolysin than did skin infections, such as erysipelas, and both throat and skin infections were greatly superior to uterine infections in this respect. Neither the level of circulating antistreptolysin at the commencement of infection nor the rate and height of response could be shown to have any bearing on the severity of the disease, except that a poor antistreptolysin response was found in certain cases of relapses and toxic complications of throat infections. This appeared, however, to be merely indicative of a general poor antitoxic response and not to have any meaning by itself, except in certain arthritic cases in which the question of its importance was more open. No correlation was noted between antistreptolysin response and relapses and septic complications in erysipelas. In general the antistreptolysin response in infection appeared to depend more on the individual than on the site or severity of infection.

**Effect of Diets Low in Choline.**—Best and his co-workers give further evidence that diets low in choline and other lipotropic factors result in the deposition of large amounts of neutral fat in the livers of white rats. There is also a small increase in the cholesterol ester fraction. The accumulation of glyceride is greatest when there are large amounts of fat in the diet, but it is observed also when there is less than the usual amount. The addition of choline to the diet inhibits the deposition of fat in the liver and the minimal effective dose of the base is less than 3 mg. per rat daily. When diets rich in fat are provided, choline appears to exert a favorable effect

on the rate of gain in weight and general physical condition of the animals. The bearing of these results on the hypothesis that choline and other lipotropic factors are essential for certain liver functions is discussed.

- Jaundice Due to Phenobarbital. C. A. Birch.—p. 478.

**Rôle of Ultraviolet Rays in Development of Cancer.**—Roffo states that among 5,000 cancer patients attending the Cancer Institute of Buenos Aires none showed cancer of any part of the skin covered by clothing (except in two or three cases in which tumors developed on nevi or burn scars). The parts of the face most often affected are those most prominent and exposed: the nose, the cheek and hardly any on the forehead. It is also found that men are more receptive (70.9 per cent) than women (29.1 per cent), the lower incidence in women being related to the care they take of their skin, protecting it with powder. Sufferers from epithelioma are generally found to have very white (photosensitive) skins, and the author has not seen a single case in natives, Negroes or mulattoes. The hyperkeratosis that leads on to the epithelioma is dominated by a photodynamic mechanism, and for fulfilment of the process the following factors are necessary: the living cell, a sensitizing photodynamic substance, the presence of oxygen and the rays of the sun. Experiments have been undertaken by the author that confirm this view. In white rats he has obtained tumors of different histopathogenesis (epitheliomas and spindle cell sarcomas) in unprotected parts of the skin (ears and ocular conjunctiva). These tumors have developed under the influence of the total sun rays or under ultraviolet rays with a wavelength of from 1,800 to 3,400 angstroms. In animals, as in human beings, the skin is found to have an abnormally high cholesterol content before the development of the tumors. Exposure to the sun's rays was in itself sufficient to produce malignant tumors in 70 per cent of the rats. The process takes from seven to ten months, passing through hyperplasia and papillomatosis, and the carcinomatous and sarcomatous animals alike die in a state of cachexia with metastases in lymph glands. Experiments performed with different rays show that the power of the rays to produce tumors depends on their actinic and not on their luminous intensity. Histologically, the lesions obtained closely resemble those observed in persons with photosensitive skins who have been much exposed to the sun. The observations emphasize the danger of such exposure.

- Papuan Field Experiment of Malaria Treatment. F. W. Clements.—p. 235.

**Neural Components of Teratomas.**—Willis discusses the possible functional significance of some of the neural elements in teratomas. The healthy appearance of many of the nerve cells in the ganglions, and less frequently in the central neural tissue of teratomas, suggests that they may have been capable of functioning. It is therefore pertinent to ask whether the nerves in these tumors may not sometimes effect functional connections with other tissues and so influence their differentiation and growth in ways comparable to those obtaining in normal ontogeny. The first step in attempting to establish this view would be to demonstrate the presence of effector nerve endings in muscle fibers and glandular epitheliums; and this has not yet been done. Finally, it is emphasized that the neural tissues found in teratomas do not form an organized nervous system. The tissues are scattered and entirely unana-

tomic in topography, neurons are scanty or absent in much of the neuroglial patches, and tracts of nerve fibers are absent; ependymal cavities are irregular in distribution and shape and are often disconnected and multiple, and peripheral nerve bundles are usually single and never grouped together to form large nerves. It is important to insist on these points, since many writers have reported that they have seen parts or the whole of a brain or spinal cord in teratomas. Structures so frequently present as masses of central neural tissue must necessarily assume, at times, shapes capable of fitting into almost any preconceived molds.

**Vitamin D in Experimental Tuberculosis.**—In order to determine the effect of small doses of vitamin D (corresponding to the doses used in clinical therapy) in the experimental tuberculosis of guinea-pigs, Zeyland and Piasecka-Zeyland performed experiments on two series of forty guinea-pigs of the same weight and age, infected subcutaneously with a dose of 0.05 mg. of bovine bacilli. In the first series of twenty guinea-pigs half of the animals after the infection received every second day one drop of a weak dilution of viosterol containing 25 international units; in the second series of twenty guinea-pigs half of the animals received every day two drops of a dilution of crystalline vitamin D containing 750 international units. By comparing the tuberculous involvement of treated and untreated animals it was possible to note a lack of convincing differences in both groups, with the exception of a slight and not essential prolongation of the life of the animals treated with vitamin D. Small doses of vitamin D corresponding to those used in the treatment of human beings, therefore, have no influence on the course of the experimental tuberculosis of guinea-pigs under the foregoing conditions.

Morbid Histology of Pulmonary Abscess Cavity Walls. S. R. Gloyne.—p. 267.

**Electrical Anesthesia in Treatment of Dysphagia.**—Grain believes that electrical anesthesia has advantages over other therapeutic methods in the treatment of painful dysphagia in that it is simple in application, painless, harmless, never producing any local or general reaction, and giving positive results in from 98 to 99 per cent of cases of dysphagia. Electrical anesthesia, as used in the treatment of painful dysphagia, is a medical anesthesia that consists in eliminating in a localized territory the pain due to evolutive or avoluted lesions. These regional pains form the extensive class of peripheral algias. The electrical anesthesia has no appreciable

and durable effect on truncular algias. It must be considered the treatment of only the algias of the nerve endings, on which it acts with remarkable efficiency. The anesthesia is obtained by iodide ionization of the larynx encircled with special electrodes. The ionization current is produced by a galvanic apparatus with a fine reducing coil working on 45-volt dry batteries or on accumulators capable of giving at least 15 milliamperes. As the current must be rigorously continuous, these sources are the only ones that can be used. The electrodes are made of unoxidable steel with a thickness of 0.5 mm. The anterior electrode is 75 mm. long and 35 mm. wide and the posterior electrode 100 mm. long and 35 mm. wide. The anterior electrode is placed in front of the larynx, and the posterior electrode on the nape of the neck. They are kept in position by a collar made of isolating thick rubber. The intensity of the current to be used is uniformly of from 10 to 12 milliamperes; the sittings last half an hour, or longer if necessary. The sittings are repeated daily until the duration of the anesthesia reaches twenty-four hours, after which they are repeated only when the pain reappears. There is no advantage in giving daily sittings once the anesthesia lasts forty-eight hours, as its progression is not influenced by the repetition. As soon as the current passes, the patient notices a sensation of stricture in the neck, and at the same time he has a taste comparable to that of ink or of copper. The sensation is accompanied by a slight amount of ptialism. The sensation of stricture disappears in four or five minutes, while the metallic taste and the salivation persist during the treatment. Five or six minutes after the passage of the maximal current the patient notices a marked diminution of the pain on swallowing, which is reduced to a sensation of slightly disagreeable prickling, and at the same time the auricular irradiations disappear. After this beginning, the anesthesia increases rapidly and in about ten or fifteen minutes after the onset of the treatment it is absolute.

**Diagnosis of Amebic Dysentery.**—Chang and his associates state that uncomplicated amebic dysentery is readily amenable to treatment. Drugs of recognized value seem to fulfil what has been claimed for them. But the success of treatment hinges entirely on an accurate diagnosis. For diagnosis, reliance has been heretofore placed entirely on the protozoological examination of the stool. In order to prevent error, even the most experienced protozoologists have insisted on a colossal number of examinations, which in actual practice is hardly practicable. To remedy this it is necessary to have a speedier and more accurate method of diagnosis to supplement, if not to replace, the fecal examinations. The authors believe that sigmoidoscopy admirably fills this need. The examination is simple and harmless and, with care, need not be unpleasant to the patient. By this method alone can one accurately observe the character of the lesion by direct vision, which in itself is often diagnostic. It ensures the most prompt detection of the causative ameba and thereby facilitates early treatment. It affords the best means of differentiation when the question of mixed infection or carrier state is at issue. It provides an accurate control of the treatment. The only drawback to sigmoidoscopic diagnosis is that in amebic dysentery theoretically the lesions may not be within the reach of the instrument. In amebic dysentery a number of questions still await answer. Among these may be mentioned the condition of the rectal mucosa in the so-called carrier state, the quantitative relationship between the lesion and the symptoms, and the comparative effect of different antiamebic preparations on the amebic ulcer. Sigmoidoscopy promises to be most helpful in unraveling these problems. An analysis of seventy-five cases of amebic dysentery and a summary of the sigmoidoscopic picture of fifty cases are presented.

**Action of Tobacco Smoke on Small Intestine.**—Simici and Popesco studied the motility of the small intestine in man by recording the peristaltic contractions of the jejunum and ileum by means of a duodenal sound and a small rubber ampule. This was attached in the usual manner to a kymograph and thus recorded. They concluded that inhalation of cigar or cigarette smoke produces in accustomed smokers as well as in nonsmokers an increase in the motility of the small intestine. It usually begins a few minutes after inhalation of the smoke. The phenomenon almost always lasts for a considerable period. It may persist for from thirty to sixty minutes after the act of smoking has been stopped. The intestinal hypermotility, which is produced by inhalation of tobacco fumes in nontoxic doses, is probably caused by the exciting action of substances in the smoke, which appear at the moment of combustion on the parasympathetic vegetative system of the intestine. The individual vegetative tonus appears to affect to some degree the intensity and duration of the response. Smoking of a tobacco filtered through a beaker containing a concentrated solution of 5 per cent hydrochloric acid loses almost entirely its property of influencing the motility of the small intestine.

**Treatment of Erysipelas.**—Meyer-Heine and Huguenin state that since the work of Mietzsch and Klarer in 1932 it has been known that 4-sulfamido-2,4 diamino-azobenzene has a remarkable action on experimental streptococcal infections. They report the action of this substance on a considerable number of patients having erysipelas of the face and of the limbs. In the majority of instances the subsidence of general symptoms and local signs occurred rapidly. This was especially true of erysipelas of the face. There were some failures but no complications of importance. In general, the hydrochloride of sulfamido-chrysoidine seems to bring about a shortening of the febrile period, causing the rapid disappearance of the cutaneous symptoms. The authors are especially impressed with the effectiveness of this treatment in erysipelas of nurslings. The mode of action of the substance is not well known, but the results seem to be undeniably good.

**Superficial Keratitis and Vitamin A.**—Stocker says that in this report he applies the term superficial keratitis to superficial changes of the cornea, regardless of whether there is inflammation or not. After mentioning various etiologic factors, he points out that he was able to differentiate one group with a uniform etiology. The general condition of these patients is usually poor; they are emaciated, pale and nervous and complain of insomnia. The superficial epithelial lesions of the cornea are of various shapes and are usually located on the lower and lateral edges and on the lower quadrant. The local treatment gives as a rule only a temporary improvement. The fact that the general condition of these patients was poor sug-

gested the possibility of a nutritional disturbance. Moreover, in view of the protective action of vitamin A on the epithelial cells and of the importance of vitamin A in xerophthalmia and keratomalacia, it was assumed that a deficiency in vitamin A might play a part in the described form of superficial keratitis, and several patients were treated with vitamin A. The result was not only that the local corneal changes disappeared but also that the general condition improved. Some of the patients remained free from relapse for a considerable length of time, but in others there were recurrences after cessation of the vitamin medication. To be sure, renewed administration of the vitamin counteracted the relapses again. Studies conducted to determine whether a carotene deficiency in the diet or a functional insufficiency of the liver is responsible for the A avitaminosis of the patients with superficial keratitis indicated not so much an insufficient intake but rather a defect in the utilization of the vitamin.

**Fractional Blood Transfusion.**—Fonio shows that the blood can be separated into its constituents: The erythrocytes can be preserved for six or seven days without hemolysis. The transfusion of the erythrocytes was well tolerated in two cases. The blood platelets can likewise be isolated and stored. However, in order to avoid the formation of agglutination, it is necessary to add a 30 per cent solution of sodium citrate. Before resorting to the transfusion of the platelets it is necessary to remove the largest part of the sodium citrate. The author suggests how this can be done but admits that as yet he has no practical experience with the transfusion of platelets. The third constituent of the blood, the plasma II, from which the blood platelets have been removed, cannot be stored for long. The author points out that with this separation of the blood into its constituents it is possible to administer that portion of the blood which is lacking or is functioning inadequately, such as erythrocytes in anemia, platelets in thrombopenia, thrombasthenia and hemophilia, and plasma in fibrinopenia or as a protein therapy. He thinks that by omitting the unnecessary substances it might occasionally be possible to avoid undesirable complications. He admits that this problem requires further biologic investigations.

**Method for Differentiating Exudates from Transudates.**—Fucci reports a test for differentiation of exudates and transudates. The technic is as follows: A decinormal solution of iodine in distilled water, a 1 per cent solution of sodium chloride in distilled water and, from this, a solution of 8.5 per thousand of sodium chloride are separately prepared. With the latter, eight solutions of soluble starch are made at 2, 1.75, 1.5, 1.25, 1, 0.75, 0.5 and 0.25 per thousand. Ten glass pipets are placed in a rack, the first eight of which are for the fluids to be examined; the other two are for controls. In each of the first eight pipets, 0.25 cc. of the unknown fluid is taken and in each of the last two (controls) 0.25 cc. of distilled water. Then 0.75 cc. of distilled water and 1 cc. of the 1 per cent solution of sodium chloride are added to each of the ten pipets. To the first eight pipets, 1 cc. of the different soluble starch solutions of the scale is added in their proper rotation. To the ninth and tenth pipets, 1 cc. of the 2 per thousand and of the 1 per thousand soluble starch solutions are added, respectively. The rack containing the pipets is placed in the incubator at 38 C. and left there for half an hour, after which it is taken out and the fluids in the pipets are allowed to cool in water or ice to the ambient temperature. Then three or

four drops of the decinormal iodine solution is added to each pipet and the reading is made. Fluids of inflammatory nature, such as pleural, peritoneal and synovial exudates, give either a yellow-whitish or golden color, which may be present in the eight first pipets or only in the last seven, with the first pipet showing a slight violet. Transudates, on the contrary, give a violet, which is more marked in the first five pipets, the last three giving a red violet. In the two control tubes, the typical violet, which indicates the starch reaction, is observed, being more marked in the first than in the second control tube, since the starch concentration in the former is larger than that in the latter. The test may be abbreviated by using seven pipets instead of ten; that is, five for the unknown fluids and two for control. The refinements of the technic are as follows: The mother sodium chloride solution should not be more than two days old. The iodine solution should not be more than twenty days old, provided it is kept in a cool place and in a colored container. The other solutions are prepared at the time of the test. The diluted fluids and starch solutions should be well mixed in the pipets before they are placed in the incubator. The contents of the pipets are well stirred after the iodine solution is added, but without disturbing the zone of initial transitory reaction. The color reading is made on the entire liquid column. The addition of a few more drops of iodine solution to the solutions in the tubes does not modify the results of the test but tends to clarify them.

\*Disorders of Apparatus of Conduction in Rheumatic Heart Diseases in Children. J. C. Etcheves.—p. 820.

**Disorders of Conduction Apparatus in Rheumatic Fever.**—Etcheves made an electrocardiographic study on a group of thirty children suffering from rheumatic fever. He concludes that disorders of the conduction apparatus are frequent in heart diseases complicating rheumatic fever, both during the acute period of the fever and after its subsidence. They may be intra-auricular, auriculoventricular and intraventricular. Intra-auricular disturbances show themselves in the electrocardiogram by alterations in size and form of the P wave, which point to the existence of auricular hypertrophy complicating mitral stenosis and, sometimes also, mitral insufficiency. A P wave of low voltage in the three leads indicates diminished functional capacity of the auricle and, if it is of the broad type and appears in consecutive electrocardiograms, it indicates both the existence of auricular insufficiency and the proximity of fibrillation. Alterations of the P wave in several leads are of bad prognostic value. Simple incomplete and complete types of auriculoventricular block are frequent in the course of rheumatic heart diseases. Those of the simple type are the most frequent, especially during the periods of reactivation of the fever. The presence of auriculoventricular block in young patients suffering from fever of unknown etiology points to the rheumatic nature of the fever, while in patients suffering from rheumatic fever it indicates evolution of the infection. Its persistence after administration of intense salicylic treatment is of bad prognostic value. Disorders of intraventricular conduction show themselves in the electrocardiogram by alterations of the QRST complex, which may involve the QRS complex, the ST segment and the T wave or only a part of the complex (the bundle branch block). In the presence of disorders of the intraventricular conduction, the duration of the QRS complex slightly increases, the Q and S waves are rarely modified and the most important alterations are those of the R wave, which, if appearing in several leads in consecutive electrocardiograms, are of bad prognostic value. The modifications of the ST segment are numerous. Most frequently it is shortened and deviated above the iso-electric line. The modifications of the T wave are frequent. They predominate during the acute phase of the fever and may per-

sist after its subsidence. An abnormal T wave repeatedly appearing in consecutive electrocardiograms is of a bad prognostic value, which becomes worse if alterations of either the P wave or the QRS complex coexist with it. Alterations of the PR wave and of the ST segment are the most frequent electrocardiographic abnormalities in the course of acute rheumatic heart disease in children. None of the disorders of the conductive apparatus, however, are pathognomonic of rheumatic fever. They all prove the involvement of the myocardium. Intraventricular disorders restricted to only a part of the conductive apparatus are those concerned in the cases of bundle branch block in which the left, but never the right, branch of the bundle of His is involved. The block of the left bundle branch is of a reserved prognosis, because it indicates the presence of grave intramyocardial and valvular lesions. The intensity of the alterations of the conductive apparatus shown by the electrocardiograms is, as a rule, in agreement with the clinical condition of the patient.

Quantitative Determination of Indican Content of Serum by Means of Step Photometer. F. Böhm and G. Grüner.—p. 450.

**Observations on Organs Years After Injection of Thorium Dioxide.**—Naegeli and Lauche describe observations on the internal organs of a dog that was killed five years after a thorium dioxide preparation had been injected as a contrast medium. The roentgenogram, which was made shortly before the animal was killed, revealed that the density of the shadows of liver and spleen had considerably decreased (comparison with roentgenogram made two years previously). However, two new shadows, which were visible beside the vertebral column, were interpreted as lymph nodes. The histologic examination disclosed no thorium in the lungs, suprarenals, kidneys and pancreas. In the spleen, the cells containing thorium were found chiefly on the trabecular margins, and in the liver the traces of thorium were found chiefly near the capsule, whereas it had largely disappeared from the deeper layers. Some of the lymph nodes contained considerable amounts of thorium and had become necrotic; others contained only small amounts of thorium. The authors reach the conclusion that the thorium, which is first stored in the liver and spleen, gradually passes into the lymph nodes and causes necrosis. To be sure, the liver and spleen did not become impaired even after five years, but neither was there any sign of an elimination of the thorium from the organism. The authors repeat their warning against the use of this contrast medium, particularly in large quantities and in young persons, for they assume that the impairment of the regional lymph nodes can be expected also in human subjects.

**Differentiation of the Blood of Normal Persons and of Patients with Exophthalmic Goiter.**—After pointing out that Reid Hunt's acetonitrile test is not quite satisfactory for the differentiation of the blood of patients with exophthalmic goiter, because it is positive also in several other disorders, György and Serény describe their own observations in the tadpole experiment. They wanted to determine whether the action exerted by blood specimens on the metamorphosis of tadpoles would permit a differentiation of blood or urine of patients with exophthalmic goiter from normal blood or urine. In summarizing their observations they say that neither normal blood or urine nor the blood or urine from patients with exophthalmic goiter influences the metamorphosis of tadpoles. Thyroxine alone, as was known from former investigations, has a greatly stimulating effect on the metamorphosis. If thyroxine is combined with normal blood, the promoting action

on the metamorphosis is lessened; that is, the normal blood reduces the stimulating action of thyroxine. The same can be said of the blood of patients with exophthalmic goiter, except that its inhibiting action is somewhat less than that of normal blood. In some cases the differences were considerable while in others they were not, and so the authors conclude that, although generally in the tadpole experiment the inhibiting effect of normal blood on the thyroxine action is greater than that of the blood of patients with exophthalmic goiter, the difference is not sufficiently clear to permit a definite differentiation of blood specimens.

**Value of Plummer's Preoperative Iodine Treatment.**—In view of the fact that some surgeons still have a somewhat skeptical attitude toward Plummer's preoperative iodine treatment in exophthalmic goiter, and in order to prevent this from deterring others from employing this valuable method, Melchior describes his own favorable experiences. He employed Plummer's preoperative iodine treatment in sixty-four cases of exophthalmic goiter. He says that his cases were of the severe type. He advises rest in bed, a chiefly lactovegetarian diet and a quieting psychotherapeutic influence during the preoperative period. He begins the iodine medication as a rule by giving five drops of aqueous solution of iodine three times a day, gradually increasing the amount to three times fifteen drops or even more. To prevent auricular or ventricular fibrillation he resorts to quinidine, and in typical cardiac disturbances he gives digitalis and strophanthin preparations. Regarding the duration of the preoperative iodine treatment, he says that it cannot be definitely established at eight or ten days but may have to be continued for several weeks. The author emphasizes that Plummer's preoperative iodine treatment exerts a favorable influence on the surgical intervention as well as on the postoperative period. In cases in which the preoperative treatment had been adequate, he saw a threatening postoperative reaction only once. He also shows that Plummer's method permits operative treatment in cases in which otherwise it would be impossible.

Protection Against Measles by Means of Placental Extract. G. Paschla.—p. 564.

**Influenza Bacilli as Cause of Meningitis.**—Bender and Bruns point out that acute suppurating meningitis in its epidemic as well as in its sporadic form is most frequently caused by the meningococcus of Weichselbaum. Observations on 537 cases indicated that approximately 71 per cent were caused by the meningococcus, 10 per cent by the pneumococcus, about 6 per cent each by the tubercle bacillus, streptococcus and staphylococcus and slightly more than 1 per cent by the influenza bacillus. The authors report two cases of influenzal meningitis, in which repeated bacteriologic tests were made. As far as the clinical aspects were concerned, the cases presented nothing unusual, but the authors emphasize that every case of meningitis should be subjected to bacteriologic examination. They deplore that influenza bacilli are not always systematically searched for and stress that the cultures, which are made on blood-free mediums and are sterile after twenty-four hours, should be given particular attention. Moreover, discharges from the ears as well as the sputum should be examined. The two cases reported terminated fatally. The influenza bacillus causes one of the severest forms of meningitis, which, according to some reports, has a fatal outcome in about 92 per cent of the cases.

**Extract of Adrenal Cortex in Treatment of Psoriasis.**—After mentioning the experiences of other investigators with extract of the adrenal cortex in psoriasis, Gruneberg describes his observations. He gives subcutaneous or intramuscular injections with from 2 to 6 cc. of the cortex extract every day or every second day. The dosage is determined by the severity of the case and the duration of the treatment by the rapidity

with which the results become manifest. As a rule, it is necessary to continue the treatment for at least five or six weeks. Some improvement is usually noticeable long before this time. The administration of the cortical extract is frequently inadequate for a complete cure and it is combined with local measures. The treatment is most effective in the form of psoriasis that is complicated by arthritic processes. The author thinks that it should always be tried in these cases. Generalized psoriasis likewise responds favorably to the adrenal cortex treatment. However, relapses are not prevented by this therapy, although prolonged treatment may have a certain after-effect, particularly in the complicating articular processes.

\*Sensitization of Neoplasms Refractory to Roentgen Rays by Means of Short Waves. G. Fuchs.—p. 473.

**Treatment of Tonsillar Cancer.**—Von Kisfaludy considers radium therapy indispensable in the treatment of tonsillar cancers. He advises that the larding with radium needles be done by an experienced radiologist who has surgical knowledge. The needles he uses contain 3.3 or 6.6 mg. of radium element. Depending on the size of the tumor, he introduces from four to ten needles and leaves them in place for from twenty-four to thirty-six hours. He maintains that this method of application is superior to the former practice of using needles that contain only 1 or 2 mg. and that have to remain in the tissues for from five to eleven days. The shorter duration of the radium application reduces the secondary irradiation, the danger of tissue necrosis, of abscess and edema formation and of general infection or hemorrhage. Moreover, it is less annoying for the patient if the radium larding remains in place only for from twenty-four to thirty-six hours instead of for a number of days. The regional glands are treated with roentgen rays: 200 roentgens are applied from six to eight times. After six or eight weeks, the roentgen irradiations of the glands are repeated. However, if the glands are enlarged, they are excised and the surgical treatment is followed by irradiation. The results obtained with this combination method prove the advantage of the author's method of larding with radium needles.

**Postoperative Irradiation of Cervical Cancer.**—Friedl shows that opinions are divided as to the value of postoperative roentgen irradiations, and he decided to investigate the cases treated at his clinic in this respect. On the whole, he observed no decided advantage in the cases that had been subjected to postoperative roentgen irradiation. The permanent results were about 5 per cent better in the irradiated cases. He suggests that, in view of this slight improvement, it might be better to look for a method promising better results, and points out that postoperative treatment with radium seems to do this.

**Sensitization of Neoplasms by Means of Short Waves.**—Fuchs cites the various methods of sensitization of ray refractory tumors which have been tried in the course of recent years. He calls attention to the vasodilatory effect and to the induction of hyperemia by short wave treatment. He decided to utilize the hyperemia in order to increase the ray sensitivity of tumors. He followed Liebesny's so-called athermic method of short wave therapy, which utilizes chiefly the electric actions and excludes largely the heat effect. He resorted to sensitization in three cases of bronchial carcinoma and one case each of mammary and esophageal carcinoma. In order to obtain an adequate depth action he worked with an electrode skin distance of at least 10 cm. The wavelength was 15 meters, and the irradiations lasted twenty minutes. They were given daily and, after an interval of two or three hours they were followed by the roentgen irradiation. The latter was conducted according to the protracted fractional method of Coutard. At every session 200 roentgens was administered to one field. It was observed that the ray reaction of the skin induced by the Coutard irradiations was neither increased nor otherwise modi-

fied by the application of short waves. Moreover, the author emphasizes that in his method the combined short wave and roentgen therapy does not involve the danger of an increase in the malignancy of the tumor. He admits that his limited experience permits no definite evaluation of the value of the sensitizing short wave irradiations, but he considers their use justified in carcinomas that are refractory to ray treatment.

\*Pathogenesis of Congenital Dropsy of Fetus and Placenta. (Placental Villi and Uterine Mucus in Vein of Umbilical Cord). J. Czyżak.—p. 807.

**Gonadotropic Function of Hypophysis During Menopause.**—Engelhart and Tscherne point out that the gonadotropic hormones of the anterior lobe of the hypophysis cause cyclic changes in the ovaries and that the ovaries in turn act on the anterior hypophysis. After the ovarian function is abolished, typical histologic changes develop in the anterior hypophysis. It has been proved that the changes in the anterior hypophysis of castrated animals can be counteracted by the administration of estrogenic substance. The authors decided to investigate this problem in women. In studies on several menopausal women they found that the administration of estrogenic substance reduces or entirely abolishes the elimination of the follicle maturation hormone of the anterior hypophysis. These studies indicate an inhibiting influence of the estrogenic substance on the anterior lobe of the hypophysis. However, there is a morphologic difference in the hypophyses of menopausal and castrated women, for whereas that of menopausal women decreases in weight, that of castrated women increases, and whereas in the hypophysis of castrated women the eosinophil cells are increased, this increase is absent in menopausal women. These morphologic differences indicate functional differences; namely, a lack of the luteinization hormone in menopausal women.

**Pathogenesis of Congenital Dropsy of Fetus.**—Czyżak reports two cases of congenital dropsy of fetus and placenta. Microscopic sections of the fetal organs revealed everywhere foci of blood formation, which were especially numerous in the liver, kidneys and adrenals. The large, edematous placenta showed an abundance of connective tissue cells and a deficiency of blood vessels. The villi were larger than usual but consisted chiefly of connective tissue cells with few and small capillaries, the lumen of which seemed to be constricted by the proliferating connective tissue. They contained only few erythrocytes, many of which had nuclei. Some lumens were entirely empty. Moreover, some of the edematous villi contained no blood vessels. Examination of the blood of fetus and mother disclosed such a similarity that differentiation was impossible. A large number of nucleated cells were found among the erythrocytes. All stages of erythrocytic development were present. The blood picture of the mother returned to normal four days after delivery. The similarity between the fetal and maternal blood pictures was explained by the aspects of the sections of the umbilical cord. Many of the sections revealed villi in the vascular lumen and others showed portions of the uterine mucosa with glands. This shows that the normal barrier of the placenta had broken down so that corpuscular elements from the maternal circulation entered the fetal circulation, and vice versa. The author thinks that this abnormal circulation is the cause for the toxic action, which in the placenta resulted in proliferation of connective tissue, obliteration of the blood vessels and edema, and which in the fetus caused severe anemia, characteristic foci of blood formation in the internal organs and generalized dropsy. The author thinks that the defect in the placenta (breakdown of barrier between mother and fetus) is a factor in the pathogenesis of fetal and placental dropsy.

What Is Certain and What Is Doubtful in Pathogenesis and Etiology of Malignant Growths. N. N. Petrov.—p. 128.

Morphogeneity of Mammal Gland Cancer. B. Kooliabko.—p. 263.

**Gastritis.**—Katsnelson and Zorina studied 100 cases of gastritis which they classified on the basis of the character of the gastric secretion into normacid, hyperacid, subacid and anacid types. They used the Ewald-Boas test breakfast and a stomach tube to remove the contents. In addition to this method, the fractional determination after a beef tea breakfast was practiced in the anacid group. In the cases in which the fractional method failed to demonstrate free hydrochloric acid, 0.5 mg. of histamine was injected intracutaneously. The cases were studied roentgenologically with particular regard to the state of the mucosal contour. The following factors were found to play an important part in the etiology of exogenous gastritis: irregular meals, excessive condiments, too hot meals, alcoholism, smoking and certain drugs as well as vocational factors. In hematogenous gastritis an important part was played by the infectious diseases, cholecystitis, ulcer and carcinoma of the stomach, and circulatory and metabolic disturbances. The clinical picture of gastritis presented a multiplicity and a variety of symptoms, while that of a pure gastric ulcer was characterized by a scarcity of symptoms. All forms of chronic gastritis, the anacid in particular, may run a latent course without causing symptoms for a long time. The authors administered histamine in twenty-seven cases of anacid gastritis and observed an increase in the free hydrochloric acid (from 0 to 0.1 or 0.44) in only 19 per cent. The quantity of the gastric juice however was considerably increased. These results suggest the existence in their cases of a severe gastritis with profound anatomic alterations in the specific secretory glands. Clinical diagnosis of gastritis was not borne out by the roentgenologic investigation in 52 per cent of their cases. The authors conclude that roentgenologic study of the mucosal relief is not of a decisive significance in the diagnosis of gastritis. The latter must depend on a careful consideration of all available diagnostic criteria.

**Relation of Gastritis to Ulcer and Cancer.**—Derman and Dudkevich studied 236 stomachs which had been resected because of an ulcerative or carcinomatous lesion. In their material chronic ulcers were localized most frequently in the pyloric portion of the stomach and along the gastric channel. Ulcerative and carcinomatous lesions of the stomach frequently exhibited inflammatory exudative manifestations in the form of an infiltration of the mucosal and the deeper layers of the wall of the stomach with neutrophils, eosinophils, lymphoid cells and plasma cells. A gradual diminution of the inflammatory reaction was noted the farther the area studied was removed from the ulcerative or cancerous lesion. The authors are inclined to consider these inflammatory manifestations secondary and complicating lesions rather than primary and the cause of an ulcer or cancer.

## RECENT EXPERIMENTAL WORK ON THE PATHOGENESIS OF MUL- TIPLE SCLEROSIS

RICHARD M. BRICKNER, M.D.  
NEW YORK

In recent years the pathogenesis of multiple sclerosis has been investigated intensively, especially in this country. The results of these observations, made in scattered places, have never been brought together. My purpose in this communication is to summarize them and to make what comparisons appear to be possible.

In the 1870's, after the disease had been made well known by Charcot, much was said concerning possible causes. Out of this discussion some views emerged, which are still of great interest. Among the most ingenious of the hypotheses was one of Pierre Marie's, which deserves rescue from the forgetfulness that has encompassed it.<sup>1</sup> Marie observed a patient who, three years following an attack of typhoid, developed multiple sclerosis; he suggested that sclérose en plaque might be a tertiary stage of typhoid in the same sense in which tabes dorsalis is recognized as a manifestation of the tertiary stage of syphilis. In the light of present day observation such an idea does not appear to be relevant to multiple sclerosis, but it may deserve consideration in respect to other more definitely infectious states, such as postencephalitic paralysis agitans.

Until recent times much of the thought about multiple sclerosis has been in terms of its being an infectious disease. Gradually, as evidence has accumulated, opinion in this country particularly has swung away from this point of view and is forming more and more what must be called a theory of toxemia. The toxemia theory is by no means a new one, however. In the 1880's it was Oppenheim's explanation; he attributed the lesions to the action of toxins—not a single toxin—most of which, he thought, were probably exogenous. In particular, he stressed lead. He had no experimental evidence; the idea came simply from the fact that many of his patients, in their occupations, were exposed to lead intoxication.

No experimental attack was made until 1913, and for good reason. Twenty years of feeling, discussion, remissions and helplessness was enough to mobilize sufficient confusion to submerge any one who studied multiple sclerosis closely. By 1896 the world was quite ready for the pleasant relaxation which the dictum of

Struempell<sup>2</sup> made possible. Struempell earned the eternal gratitude of those who had thought to the point of exhaustion when he declared that he felt that multiple sclerosis was due to an inherent, congenital tendency of the glia to overgrow, the overrunning glia demolishing the myelin sheaths. Struempell had no shred of evidence for this idea; it was chiefly that he had seen no cases that could be explained by lead poisoning or by typhoid. But the doctrine became galenic. It was accepted as the truth, and for seventeen years workers, faced with the impenetrability and hopelessness of this dogma, rested. In passing, it is of interest to note that this highly sterile paper closed with a short paragraph in which was noted for the first time the important fact that the abdominal reflexes were lost in 67 per cent of the cases of multiple sclerosis.

In 1913, Bullock (now Gye),<sup>3</sup> investigating the possible infectious nature of the disease, made the first experimental attack. He inoculated rabbits and guinea-pigs with spinal fluid from patients with multiple sclerosis, and although he appeared to have transmitted the disease to some of the animals and although there has been some confirmation of his work, many have declared that there were faults in his technic. Despite these and the inoculation experiments of other workers, it still cannot be declared that multiple sclerosis has been experimentally produced in animals by inoculation.

The idea of infection has been more fully explored by Kuhn and Steiner,<sup>4</sup> and later by Steiner alone.<sup>5</sup> This investigator has for many years studied the possibilities of a spirochetal origin. He apparently has occasionally demonstrated spirochetes in the neural tissue in cases of multiple sclerosis. More commonly, he has been able to show what he believes to be the remains of disintegrated spirochetes. If Steiner's spirochetes were more numerous in any given case the results would be more convincing. An observer is impressed with the resemblance to spirochetes of some of the stained structures but misses the profusion of organisms which is seen in syphilis. Steiner himself believes that the scarcity of organisms is due to his having had an opportunity to examine only old cases; he has studied no specimens from individuals who had died while the process was, presumably, still fresh. Although several investigators appear to have confirmed Steiner's work, a number of others have failed to do so. The time has not yet arrived for final conclusion concerning Steiner's observations. His studies are the only contemporary ones that give any real support to the infectious theory.

The recent announcement of Sachs and Steiner<sup>6</sup> of a complement fixation test for the disease is not necessarily confirmatory of the spirochetal theory.

The Purves-Stewart-Chevassut spherula insularis has long since been entirely discarded.

The toxemia point of view has gained support in recent times from several sources. Investigations in the last few years have produced evidence for it, although, both individually and collectively, the results of all these studies must still be regarded with conservatism. The term "toxemia" is used here in a broad sense, referring to the action of any myelinolytic substance, or even condition, on the myelin sheaths. This substance or condition need not be toxic for any structure in the body other than the myelin sheath. It need not be one single substance—there may be a variety of them, all having the same capacity to cause myelin disintegration. From the standpoint of toxemia, the active agent would not be of an infectious nature. This conception also implies that the myelin does not degenerate because of a progressive gliosis.

As an introduction to such a toxemia theory, it would be well to refer to the conceptions of Hallervorden,<sup>7</sup> although his papers appeared at a later date than some of the other works to be discussed. Hallervorden was much impressed by the pathologic appearance of a case described in 1928 by Balo.<sup>8</sup> Later Hallervorden and Spatz<sup>9</sup> described two additional similar cases. The lesions were chiefly in the form of concentric rings of demyelination, and in the center of each focus was a blood vessel. Hallervorden recalled the earlier (1898) experiments of Liesegang, who had performed a series of tests. He dissolved ammonium or potassium bichromate in gelatin; drops of silver nitrate were placed on the surface of the gelatin. The silver nitrate, diffusing into the gelatin, reacted with the bichromate to form the dark silver chromate. But instead of forming as a solid black mass the silver chromate appeared in concentric rings. This was explained as follows: The silver nitrate reacted with the first bichromate it encountered, forming the black silver chromate. The resultant silver chromate adsorbed the additional adjacent bichromate. Thus, a zone was left without any bichromate. The silver nitrate, diffusing into this bichromate-free area, had nothing to react with, so that this zone remained uncolored. The next black ring was formed at the point at which silver nitrate again came into contact with bichromate. The whole reaction was repeated again and again.

Hallervorden, seeing an analogy between Liesegang's chemical experiments and Balo's case, came to the belief that in that case the myelin had been caused to disintegrate precisely in the same way that Liesegang's rings were formed; namely, by diffusion of a demyelinating agent from a central point. This would imply that the neural tissue, in its living state, served as an inert colloid comparable to Liesegang's gelatin. Hallervorden was ready to adopt this as a hypothesis.

Hallervorden bridged the gap between Balo's disease and multiple sclerosis by quoting a case of Steiner's in which, besides the orthodox type of plaque, there was one in which the demyelination took the form of concentric rings. He thought that the rarity of this con-

centric arrangement in multiple sclerosis was not a convincing argument against the diffusion principle, since diffusion through colloids can, of course, take place in various ways, and not necessarily with the production of concentric rings. He considered that he had presented a fair argument for the general principle of diffusion as the mechanical background in many types of demyelinating disease, including multiple sclerosis. There is no doubt that Hallervorden's ideas are interesting and should serve as a part of the toxemia conception of multiple sclerosis, even though nothing was actually proved by his work.

Actual testing of the toxemia theory has been carried out in two main ways. One approach has been the attempt to produce demyelination in animals by the injection of any toxins which would yield results. The other has been the effort to identify a certain toxin, the presence of which is suspected—a toxin with specific lipolytic action. It can be said at this point that, while each of these approaches has yielded information, neither has solved the problem.

The only investigator who has directly produced demyelination by experimental toxemia is Ferraro.<sup>10</sup> He injected small doses of potassium cyanide into monkeys and cats and, in the majority of instances, obtained multiple areas of demyelination. It is of considerable interest that some of his lesions had the concentric appearance to which Hallervorden gave so much thought. The idea of using potassium cyanide as the toxin is not far fetched, although it might seem to be at first consideration. Ferraro observes, apropos of the metabolic rôle played by cyanide:

Cyanide is part of our intermediary metabolism and, according to Werner, the hydrolysis of urea by acids or bases would result in a dissociation into ammonia and cyanide acid. According to A. P. Matthews, in the course of biological oxidations isocyanic acid may be formed, which undergoes rearrangement with ammonia into urea. Salkowsky also believes that urea may be formed by the transformation of cyanamide, and Fosse considers cyanic acid the immediate precursor of urea.

Recently Brand and Harris expressed the belief that on the basis of the cyanic acid theory of Salkowsky, Werner and Fosse creatine may possibly arise from a side reaction between cyanic acid and glycine.

Intensive work has also been done by Putnam and his collaborators<sup>11</sup> in the use of toxins, but from a modified point of view. They have produced patchy demyelination in dogs by the employment of tetanus toxin, carbon monoxide poisoning and the injection of cod liver oil emulsion resulting in the formation of emboli.

From all these results it seems quite clear that patchy demyelination can be induced in the intact animal by the injection not only of toxins but of different toxins, and perhaps by a variety of mechanisms. Putnam's explanation, however, does not invoke the direct action of the toxin on the myelin. He believes that these substances exert their effect by producing venous emboli or thrombi, which, by causing a slight relative anemia, induce local myelin disintegration. That this is possible has been shown by Putnam, in experiments with the injection of bland, oily substances against the blood stream into the ligated longitudinal sinuses of dogs. Perivenous demyelination was the outcome. The

presence of such thrombi in the nervous systems of individuals dying with multiple sclerosis is also attested by Putnam. It should not be understood, however, that Putnam believes that thrombi are necessarily the result of toxic action in the human patient. He remains, at present, uncertain as to their origin.

Still another modification of the general toxic approach has been that of Rivers and Schwentker.<sup>12</sup> He has recently produced patchy demyelination in monkeys by the frequently repeated intramuscular injection, over a long period, of an alcoholic extract of brain lipoids. In this study the authors considered that they were working with an allergic process. They believed that they were administering an antigen to which the neural myelin might be sensitive. Actually, this may not be the explanation of the results. It is perfectly possible that a straightforward toxin was being given which acts, perhaps in the same general way as the toxins used by Ferraro and by Putnam.

These are the well controlled pieces of work which have been done in the production of experimental demyelination. There is no question that they have produced results.

The difficulty with this type of approach, as it has thus far been used, is, in my opinion, a very serious one. It is impossible to link the experimental results with the disease or syndrome of multiple sclerosis except by syllogistic argument. It can indeed be said that pictures resembling multiple sclerosis have been produced in animals, but the disease itself has not. This will be accomplished only when patchy demyelination has been caused by the injection into animals of material obtained from human patients. This, of course, is not the only criterion, but it is a prerequisite to all others. Steiner's work, and some of the earlier attacks from the standpoint of infection, did make use of human material, but, as has been stated, these efforts still lack final confirmation.

A different type of approach to the toxemia theory has also been made. The attempt was not to produce experimental demyelination but to consider patients themselves in an effort to learn whether demyelinating agents or conditions might exist in vivo.

From this standpoint, Cone, Russel and Harwood<sup>13</sup> have made an inquiry into the rôle of lead poisoning in multiple sclerosis. These authors conceived the ingenious idea that the periods of exacerbation and of remission in multiple sclerosis might be associated with the mobilization into the circulation, and the removal from it, of lead. Their studies yielded some evidence that such may indeed be the case. The chief obstacles to final acceptance of their idea are two: the difficulty inherent in quantitative estimations of the amount of lead present in body fluids, and lack of information concerning the amounts of circulating lead which should be considered normal for a given individual. As these matters are gradually elucidated, the part played by lead in multiple sclerosis will undoubtedly be better understood.

The suggestion was made by Marburg, many years ago, that the lesions in multiple sclerosis might be the result of the action of an enzyme which destroys lecithin. No attempt was made to investigate this idea until 1929, when, in ignorance of Marburg's idea,<sup>14</sup>

I commenced an experimental attack from the same point of view. The plan was to seek not particularly a lecithinase but a lipolytic agent of any sort which might affect myelin. The first experiments consisted in the immersion of segments of the spinal cord of rats in blood plasma from patients with multiple sclerosis. Sections of these cords after twenty-four hours of such immersion showed that multiple sclerosis blood had a demyelinating action which was not demonstrable in blood from controls. The part of the blood which gave the best results was the plasma. The results were very suggestive but not sufficiently marked. They did indicate that the blood of patients contained something which had a demyelinating potentiality. Weil and Cleveland<sup>15</sup> were able to confirm these observations, although they employed serum instead of plasma and used a different method of studying lipolysis.

From that time until the present, the inquiries from this point of view have been of a chemical nature.<sup>16</sup> The aim has been to learn whether the apparent difference between the lipolytic activity of multiple sclerosis and control blood could be more firmly established. Two different types of chemical attack have been made, and both have indicated that such a difference does exist. Serum has been employed instead of plasma, as a matter of convenience. The working principle has always been the mixture of the serum with a lipid. Lecithin was used as the substrate in one series and certain esters were used in the other. Measurement was made of the degree to which the lipid was broken down by the serum. This was easily done by estimating the amount of fatty acid produced in the mixture after an incubation period of twenty-four hours. It was always found that there was a decided difference between the various characteristics of the lipid breakdown caused by the action of multiple sclerosis and of control serums. The manner in which these differences showed themselves is intricate and elaborate and it is not essential to relate them here. The chief difficulties with these results are their complexity of interpretation and the fact that it has always been necessary to make the comparisons in groups. It was always a group of control serums that had to be contrasted with a group of multiple sclerosis serums. It was never possible to obtain results sufficiently sharp to enable one to identify a given case as one of multiple sclerosis. The continued search for a method which could accomplish this has led to an unexpected observation, which will be discussed later.

While these studies were proceeding, Weil<sup>17</sup> and Crandall and Cherry<sup>18</sup> of Chicago were interested in similar conceptions. Crandall and Cherry reported in 1932 that they could confirm my results in the investigation of lipolytic activity. They also found differences between multiple sclerosis and control bloods when the lipolytic action was tested. Their method differed partly in the employment of olive oil as a substrate and their interpretation was totally different. They made the suggestion that the lipolytic changes might be dependent on liver damage.

14. Brickner, Richard: Studies on the Pathogenesis of Multiple Sclerosis, *Arch. Neurol. & Psychiat.* 23: 715 (April) 1930.

Accordingly, Weil and Crandall<sup>19</sup> ligated the cystic or pancreatic ducts in dogs, following which they frequently obtained demyelination in the nervous system of the animals. A demyelinating substance was also demonstrable in the blood, as tested by the rat cord immersion method. This material was declared not to be an enzyme, since it survived the effects of heat and since its presence appeared to be independent of the level of other lipases in the blood.

Karady<sup>20</sup> has also confirmed the finding of lipolytic abnormalities in multiple sclerosis serum. He has gone further and demonstrated lipasic changes in the duodenal contents in multiple sclerosis.

In addition, Weil<sup>17b</sup> has looked for a "myelolytic toxin" in the urine of patients with multiple sclerosis. He has found it, according to tests made with the rat cord immersion method. He states that it too is thermostable and is therefore not actually an enzyme.

Further study is required for the elucidation of these points. The same is to be said for my own investigations. Granted that a difference exists between the ability of blood from control and that from multiple sclerosis patients to split various lipoids, of what does this difference consist? There are a number of possibilities, and the profession is not in a position to choose between them. The alternatives are:

1. That the action is that of an enzyme. If it is an enzyme, it may be

- A. An abnormal enzyme.

- B. A normal enzyme in abnormal quantity.

- C. A normal enzyme in normal quantity, but in an abnormal milieu, which makes it act in abnormal fashion.

2. If it is not an enzyme, it may be

- A. A foreign substance with lipolytic power.

- B. A normal lipolytic substance in abnormal quantity.

- C. A normal lipolytic substance in an abnormal milieu, which causes it to act abnormally.

In addition, it has not been proved that this abnormal lipolytic activity is actually of primary importance in the pathogenesis of multiple sclerosis. It accompanies multiple sclerosis, but it may still be a by-product of some other process.

It may be seen, then, that the present status of knowledge of the cause of multiple sclerosis is not very satisfactory. Part of the confusion may be due to uncertainty as to whether multiple sclerosis is really a disease entity, with one single cause, or whether it is a syndrome which may be produced in a variety of ways. It seems likely that some of the studies described, when carried further, may help to clarify this phase of the matter. Moreover, some experimental data concerning the disease have been obtained, and it is interesting to evaluate the general trends that they indicate. Is there anything in common between these various endeavors?

They do, in united fashion, emphasize the growing belief that there is little general evidence in favor of an infectious origin for multiple sclerosis. The usual absence of fever except in acute cases, the absence of evidence pertaining to contagion and the lack of any convincing indications of infection on microscopic study of the lesions all form a background for this trend—a belief which has been stressed by others in this country, notably by Hassin. Even the occasional out-

break of multiple sclerosis after a general infection must be interpreted with reserve. The explanation may well be that the infection merely excites the process, without causing it, just as trauma may do. Certainly it is common to see exacerbations, in well established cases, after incidental infections or trauma. Also, some of the approaches furnish support for the idea that a toxemia, operating by one mechanism or another, is at least capable of explaining the diffusely scattered lesions of the disease.

In what manner may the lipolytic investigations be related to the others? Some very general theoretical statements about this can be made. As has been stated, Putnam recently reported the finding of thrombi in many of the smaller vessels close to plaques. If Putnam's observations and conceptions find substantiation, the causation of the thrombi has yet to be explained. But Weil has pointed out that many different toxins, which are at the same time hemolytic, may cause demyelination of nerve fibers, as tested by the rat cord immersion method. It is not impossible that the lipolytic material with which Weil, Crandall, Cherry and I have been working is active not only on the myelin sheath but also on the erythrocytes. Conceivably such erythrocytic alteration could lead to the formation of Putnam's thrombi.

Some additional recent work has been related only indirectly, if at all, to the pathogenesis of multiple sclerosis. It is more directly concerned with serologic and blood chemical factors, in their relation to activity of the disease as contrasted with inactivity.

Sachs and Steiner<sup>6</sup> have announced the discovery of a complement fixation test for multiple sclerosis which is comparable to the Wassermann reaction. The facts appear to be impressive, and if the results are confirmed an extremely important step will have been made in the advance on the disease. It would not necessarily mean that the disease is a spirochetal or even an infectious one, but it would serve as a quick and convenient method of diagnosis and of estimating activity or inactivity of the disease. It could also be used as a check on therapeutic procedures. For all these reasons it would be a most useful tool in the further investigation of the etiologic factors responsible for the disease. The relations between the lipolysis studies and the complement fixation reaction would also require elucidation.

The most recent phase of the work on lipolytic action has been concerned with the changes occurring in the blood during remission.<sup>21</sup> A new technic has been employed, and it is probable that we are working with a different lipolytic agent than before. In these experiments the results can be summed up as follows:

1. The agent has been proved to be enzymic in character. Since the substrate used was an ester (methyl butyrate) the enzyme is an esterase.

2. In active multiple sclerosis the degree of serum esterase activity is low. (Clinical activity of the disease is estimated in the following empirical manner: minimal activity is existent if there has been at least one new symptom within the previous four months and this new symptom has not improved; a case is inactive if there have been no new developments within four months or if all the symptoms have improved and there have been no concomitant regressions in that interval.)

3. During inactivity the degree of serum esterase activity is high.

4. It appears to be true, although the definite assertion cannot be made at this time, that the action is

19. Weil, Arthur, and Crandall, Lathan: Die Beziehungen zwischen Lipasehalt und der neurotoxischen Wirkung des Serums nach experimenteller Leberschädigung. *Ztschr. f. d. ges. Neurol. u. Psychiat.* **140**: 572, 1932.

20. Karady, I.: Studies on the Lipase Contents of the Duodenal Juice and the Serum in Multiple Sclerosis. *Orvosi hetil.* **78**: 394 (May 5) 1934.

21. Brickner, Richard: Blood Esterase Changes Associated with Clinical Activity and Inactivity in Multiple Sclerosis. *Bull. Neurol. Inst.* to be published.

greatest at the beginning of inactivity and is gradually reduced as inactivity continues. At all events it rarely, if ever, reaches the low range shown by active cases.

5. In a few cases studied during activity, and again after inactivity had begun, the indicated change was quite abrupt.

6. The experiments show that the presence of a small amount of quinine hydrochloride in the flask containing the serum and the ester stimulates the action of the esterase. Thus, the first actual experimental support for quinine therapy in multiple sclerosis is obtained.

7. The observations may be useful

A. In improving one's knowledge of what happens during remissions. It is quite possible that the high esterase value is connected with the repair of injured myelin.

B. As a test of activity of the disease.

C. As a standard by which to evaluate therapeutic investigations.

#### CONCLUSION

It seems fair to say that there is enough information at hand even now to justify the hope that investigators are heading in similar directions and that union and solution may not be too far distant.

## FRACTURES OF THE PATELLA

### RESULTS OF TOTAL AND PARTIAL EXCISIONS OF THE PATELLA FOR ACUTE FRACTURE

WILLIAM E. BLODGETT, M.D.

DETROIT  
AND

ROBERT D. FAIRCHILD, M.D.

ROCHESTER, MINN.

It is our purpose in this paper to present a new conception of the treatment of the acute fracture of the patella. The ideas herein set forth have been used in a sufficient number of instances in a large charity service and in the private practice of one of us (W. E. B.) to warrant our bringing them to the attention of those treating this type of injury.

That the treatment of fractures of the patella is still open for discussion is attested by the number of procedures recently devised for dealing with the condition. It is noteworthy that all the newer methods aim at a more rapid restoration of the patient to economic usefulness.<sup>1</sup>

Following the lead of Gallie and LeMesurier,<sup>2</sup> procedures using fascial transplants have been described by Allen,<sup>3</sup> Haggart,<sup>4</sup> and Leavitt.<sup>5</sup> They all involve the preparation of another operative field to obtain the transplant but in hands of the aforementioned writers are productive of good results. Ober<sup>6</sup> uses narrow strips of the aponeurosis of the extensor tendon above the proximal fragment, where they are secured and then passed longitudinally through drill holes in the upper fragment and attached to the periosteum of the lower

fragment and the patellar ligament. Anderson<sup>7</sup> proposes a pin method combined with opening of the fracture site to remove clots and prolapsed patellar capsule.<sup>8</sup> Recent textbooks do not mention the management advocated by any of these authors but confine their descriptions to the older methods of open reduction and suture of the fragments<sup>9</sup> or cerclage with silk.<sup>10</sup> The older treatment<sup>11</sup> of open reduction with drilling and suture of the fragments by wire, kangaroo tendon, or catgut are in standard use<sup>12</sup> and have been unchanged essentially for nearly seventy years.<sup>13</sup> The fragments of the patella are drilled transversely or longitudinally and are held in place by silver wire,<sup>14</sup> phosphobronze wire,<sup>15</sup> and various absorbable materials.<sup>16</sup> The fragments are sometimes held in place without bony fixation,<sup>17</sup> or by cerclage.<sup>18</sup> With a small comminuted lower portion, the proximal fragment may be drilled longitudinally, a kangaroo tendon placed in the patellar ligament about the distal comminuted area and this drawn up through the drill holes and tied at the proximal end of the large fragment.<sup>19</sup> This method proposed by Thompson is a good treatment and excisions of the lower fragment are discussed later.

Old fractures of the patella, if the fragments cannot be readily freshened, approximated and sutured,<sup>20</sup> are the subject of ingenious operative procedures requiring better than average surgical skill.<sup>21</sup> We suggest that the removal of the upper fragment or of the whole patella in these cases with the fashioning of a new extensor tendon from adjacent quadriceps fascia might be as efficient and is surgically a less formidable undertaking.<sup>22</sup>

We are not concerned here with the problem of the treatment of the acute fracture of the patella when open reduction is contraindicated.<sup>23</sup>

We have not seen a frontal fracture of the patella.<sup>24</sup> Fractures of the patellar border without displacement,<sup>25</sup> longitudinal fractures,<sup>26</sup> certain stellate fractures and transverse or oblique cracks without displacement of the fragments are treated by us with a walking-iron cast to the mid thigh and immobilized in extension for from six to eight weeks. No record of these cases is included in this paper. Compound fractures<sup>27</sup> are treated conservatively until infection has cleared and then sutured or excised, depending on the operator. Simultaneous bilateral fractures of the patella<sup>28</sup> occurred in five of our cases and are summarized in table 4.

All the methods previously referred to for the open reduction of the patella contemplate the accurate reposition of the fragments and their fixation by various means with longer or shorter periods of immobilization, depending on the operator and the type of procedure used. Bony union is the criterion of success, although close fibrous union is usually functionally as efficient.<sup>22</sup> The patella, of all bones, is the most susceptible to refracture.<sup>29</sup> It is important and sometimes difficult to get exact reposition of the posterior articular surfaces of the fragments.<sup>30</sup> When a foreign body such as wire is introduced for suture material, this must sometimes be removed, and it may cause rarefaction of the bone.<sup>31</sup> Adhesions to the femur sometimes complicate the end result.<sup>32</sup>

TABLE 1.—Age Distribution of the Patients in a Series of Fifty-Five Fractured Patellas

Age	Cases
11 to 20.....	2

31 to 40.....	16
41 to 50.....	13
51 to 60.....	11
61 to 70.....	4

To obviate these difficulties, the method of subtotal resection of the patella or, when indicated, total excision of the patella is proposed. Briefly we advocate the excision of the upper fragment or fragments in those cases in which there is a sizable lower fragment left for attachment of the quadriceps tendon and aponeurosis. In those instances in which the patella has been markedly comminuted with wide separation of the fragments and a sizable lower fragment is not left, we advise the removal at once of the whole patella.

Neoplasms and granulomas of the patella have been dealt with by excision<sup>33</sup> but as far as we know partial or total excisions of the patella have never been advocated as primary measures in the acute fracture. Heinech<sup>33</sup> quoted a series of twenty-one excisions of the patella for various disorders and seven of these were com-

minuted fractures. He strongly opposed the excision of the kneecap on cosmetic and functional grounds and lamented the loss of protection to the knee joint. The foregoing series were from the literature up to 1909.)

The rationale of the removal of the upper fragment or fragments of the patella for acute fracture calls for some discussion. Although the end result of the removal of the lower fragment was excellent in two of three cases in which this operation was performed and the end result in the remaining case was unknown, we do not think that the removal of the upper fragment of the patella is a wise procedure. The extensor apparatus of the knee is composed of the quadriceps extensor group of muscles, the patella and the patellar ligament. The patella itself, owing to its attachment to the inelastic patellar ligament, moves very little if any proximally or distally in movements of the knee joint. Furthermore, the apex of the patella is embedded in the patellar ligament and in the infrapatellar fat pad. Thus the lower end of the bone is fixed and is analogous to the olecranon process of the ulna in this regard. On the other hand, the base of the patella receives the insertion of the rectus femoris tendon and the tendon of the lateral vastus muscle. Muscle fibers and aponeurosis of the medial vastus muscle and the medial and lateral retinacula patellae are likewise inserted into its medial and lateral borders respectively and form the walls of the knee joint capsule. In any operation for fracture of the patella, whether it is excision or some one of the suturing procedures, it is imperative that we be very careful to suture the lateral and medial rents in the knee joint capsule. The success or failure of this one factor will determine the difference between a fair result and one that is excellent.<sup>34</sup> Provided then that one has been careful to suture the tears in the knee joint capsule up to the sides of the patella, it can matter little if one removes the fragments above the line of fracture and the suture line in the capsule. We do this instead of attempting a doubtful repair with drilling of small fragments or encircling them with the likelihood of getting only a fair anatomic result and often one which does not lead to bony union.<sup>35</sup>

The patella glides on its posterior surface on the intercondylar notch of the femur and is interposed between the extensor muscles and the patellar ligament, helping as it were to guide the extensor action from the thigh to the anterior tubercle of the tibia. The results of the removal of the upper third, upper half, or upper two thirds of the patella or, in fact, the whole patella with suitable indications, would not be productive of serious consequences. In kneeling,<sup>36</sup> the pressure comes on the patella and the anterior tibial tubercle and in partial removal of the patella, even up to two thirds, the protection to the knee joint from knee-high objects could hardly be said to be lost. If the patella is removed, of course, the condyles of the femur and the tibial condyles are somewhat more exposed to direct trauma than formerly. By sharp dissection close to the bone, the extensor apparatus is preserved for attachment to the patellar ligament when a total excision operation has been performed or for attachment to the fascia and periosteum in front of the remaining fragment, where a subtotal excision has been done.

Interrupted sutures are used throughout, as it is felt that the mattress suture produces a dehematization of

the tissues incompatible with quick healing of the extensor apparatus. In the first few cases and in an occasional later case, attempts were made to reform a "socket" of peripatellar tissue in cases of total excision of tissue from about the fragment removed to provide for the regeneration of a new patella. These "patellar-

\* Of the total of thirty-five operated on in this manner, the results in twenty are listed as unknown, as stated in the text.

plasties" were abandoned and simple suture of the patellar ligament and extensor aponeurosis was carried out with equally good results.

The skin incision may be any one preferred by the operator provided there is adequate exposure of the whole extensor apparatus, including the lateral ligaments of the knee joint.

Following operation, it is our custom to apply a posterior mold or a cast to immobilize the knee in full extension. If the postoperative course is uneventful, passive motion is started on the ninth or tenth day and the patient is gotten out of bed. This is followed by passive motion three times daily for four days and then active motion with the patient up and about on crutches. Weight bearing is started any time after two weeks following the operation. The patient leaves the hospital with a tight flannel bandage about the knee and crutches or cane to steady him rather than to take much of his weight. From then on his recovery is rapid and most of these patients can do light work within from six to eight weeks following operation. Work requiring stair climbing or heavy manual labor is prevented by a certain amount of pain and stiffness residual in any severe knee injury. In the younger group of patients, heavy work can be done at the end of three months.

Most of the operations proposed for the suture of the patellar fragments are followed by a period of post-

operative immobilization varying from four to twelve weeks. In those more recently described procedures which involve the use of fascial transplants, there is always a question whether the fragments are going to stay in place once they have been put there and whether the transplant is going to be an effective immobilization during those early weeks when the fracture line is strained by any motion. Conversely, it is highly important to secure early motion in order that function will return as soon as possible.

During the three year period Jan. 1, 1932, to Jan. 1, 1935, there were fifty-five fractures of the patella submitted to open reduction at the Receiving Hospital. As already stated, certain fractures were treated by closed methods. Our records do not show the total number of these but we estimate it to be upward of twenty. In the whole series there were forty-four males and eleven females. Forty-eight were white, six were Negroes, and there was one Oriental. The left patella was involved in twenty-seven, the right in twenty-three, and both patellas in five. The Wassermann reaction was positive in four, negative in forty-five, and not recorded in six. An "automobile accident" was the cause of injury in twenty-six, those riding in an automobile numbering twenty-four, and those being struck by one two. Four were injured in fights or in playing ball, and the remaining twenty-five had a history of a fall.

TABLE 3.—Summary of Twenty Cases in Which Various Excision Operations Were Carried Out

Case	Patient	Race	Sex	Age, Years	Observed	Operation	Result
1	S. A.	White	♀	42	.....	Excision	Unknown
2	E. B.	White	♀	53	.....	Excision of upper fragment	Unknown

13	P. L.	White	♂	30	7 mos.	Excision	Good, improving
14	E. M.	White	♂	57	.....	Excision of lower fragment	Unknown
15	A. M.	White	♂	27	.....	Excision of upper fragment	Unknown
16	J. N.	White	♂	59	18 mos.	Excision of upper fragment	Excellent
17	A. N.	White	♂	33	7 mos.	Excision	Good, improving
18	C. O.	White	♂	50	.....	Excision	Unknown
19	A. R.	White	♂	39	22 mos.	Excision of upper fragment	Excellent
20	W. W.	White	♂	35	6 mos.	Excision of upper fragment	Good, improving

The age groups are summarized in table 1. A general anesthetic was used in all but four, in whom spinal anesthesia was employed.<sup>10</sup>

Thirty-five of these patients were operated on by various members of the staff with the older methods of bone suture with chromic catgut or kangaroo tendon or merely suture of the capsule. Of these thirty-five, a total of fifteen returned at our request for reexamination and the end results are summarized in table 2.

Although many of the remaining twenty were observed in the outpatient department for varying periods, the end result is listed as unknown because we had not personally examined them. An excellent result was one in which the patient had essentially as useful an extremity as before operation. A good result was one in which the patient was improving with use and had nearly full flexion and only moderate difficulty in getting up and down stairs or in doing his work, if he had any. All other results were fair, there being no instances of over 50 per cent impairment of function but economic usefulness was often considerably diminished, because the patients were laborers. A straight transverse incision was used in fourteen cases, a curved<sup>37</sup> semicircular incision with the concavity downward in nineteen and with the concavity upward in one. A longitudinal incision was used once.

Twenty patients had total or partial excision of the patella; in nine the upper fragment was removed, in three the lower fragment, and in eight a total excision

TABLE 4.—Summary of Cases of Simultaneous Bilateral Fractures of the Patella

Case	Patient	Race	Sex	Age, Years	Observed	Operation	Result
1	F. D.	White	♂	65	24 mos.	Excision of lower fragment (right) No displacement, east (left)	Excellent
2	E. J.	Negro	♀	29	...	Suture capsule (right) Suture capsule (left)	Unknown
3	S. L.	White	♂	10	.....	No displacement, east (right) Suture capsule (left)	Unknown
4	J. N.	White	♂	17	....	Kangaroo tendon through fragments (right) Kangaroo tendon through fragments (left)	Unknown
5	A. R.	White	♂	29	..	Kangaroo tendon through fragments (right) Excision of upper fragment (left)	Excellent

of the patella was done. These cases are summarized in table 3. Eleven of these patients returned at our request for personal examination, the remainder being listed as unknown. A longitudinal incision was used in seven instances, a curved longitudinal incision in six and a transverse semicircular incision with the concavity downward in seven.

A review of the hospitalization required for these two series showed a substantially shorter time for the patients having excision procedures. This may be accounted for by the fact that we see no advantage in delaying operation, if the skin is clean, beyond from three to four days.<sup>37</sup>

The question of the regeneration of the patella has been of interest in view of our attempts at "patellar-plasty." Certain of the roentgenograms of the knees from which the patella had been removed sometime previously showed small scattered areas of calcium density in the region of the patellar ligament and extensor tendon. This was not taken to indicate regeneration of the patella.<sup>38</sup>

The preoperative care of these knees<sup>39</sup> consists simply of immobilization in extension by any means, it being our custom to use a posterior yucca board splint

from the toes to the mid thigh to prevent further damage to the medial and lateral knee joint capsule.

The following reports of cases are given to illustrate certain points and are typical of the whole series of total and partial excision procedures:

CASE 1.—G. B., a white man, aged 36, admitted to the hospital, Nov. 21, 1932, had fallen on his right knee, and radiographic examination revealed a comminuted fracture of the patella with separation of the fragments. At operation, November 26, the patella was removed subperiosteally. There were eleven fragments in all. The extensor tendon and patellar ligament were sutured and the lateral tears in the knee joint capsule repaired. He was given the routine postoperative care and at our request returned, Oct. 27, 1934, at which time he had full, painless flexion and extension, walked up and down stairs normally and worked at hard labor. He could raise himself from a half squatting position with the operated leg alone and he was well satisfied.

The multiplicity of fragments found in case 1 would have almost precluded drilling and suturing. The end result justifies the excision of the patella in this case for markedly comminuted fracture.

CASE 2.—P. L., a white man, aged 30, was injured when sliding to base in a ball game, and on radiographic examination of the left knee a transverse fracture of the left patella with marked comminution of the lower fragment was demonstrated. At operation, Oct. 8, 1934, four days following admission, the patella was excised and a "pocket" formed of the peripatellar tissues. The capsule of the knee joint was sutured and a cast was applied. The latter was bivalved and the patient left the hospital nine days after operation with the posterior portion in place and the foot of the cast cut off to permit his wearing a shoe. Tight flannel bandage protection alone was started on the twenty-third day after operation. The patient was reexamined, May 3, 1935, and was found to have full, painless extension against gravity and flexion to 90 degrees. He was working steadily as helper to a truckman. Radiographic examination showed removal of the patella and three small areas of calcification in the region of the patellar tendon.

In this case no regeneration of the patella was found on radiographic examination of the left knee six months after excision, and the disability following fracture of the patella and excision had practically disappeared.

The two reports to follow are presented because they are instances of simultaneous bilateral fracture of the patella,<sup>40</sup> and the patients reported for reexamination at our request (table 4):

CASE 3.—F. D., a white man, aged 65, admitted Oct. 12, 1932, had been injured in an automobile accident with fractures of both patellas. Radiographic examination revealed stellate fracture of the left patella without displacement of fragments and comminuted fracture of the right patella with considerable separation of the fragments. Clinically the patient could raise the left leg but not the right. Five days after admission the lower fragments of the right patella were excised and the left leg was put in a cast from the toes to the mid thigh. Passive motion to the right knee was started in ten days and active motion three weeks after operation. A flannel bandage about the right knee and the cast on the left leg necessitated the use of crutches during his convalescence. The cast to the left knee was removed at the end of nine weeks. At examination, Oct. 27, 1934, he had full, painless flexion and extension, he walked up and down stairs normally, and both knees were as useful as before operation.

This case illustrates an excellent result of excision of the lower fragment, but we do not now advise this procedure, as we have already stated.

CASE 4.—A. R., a white man, aged 39, fractured both patellas in a fight, and radiographic examination revealed transverse fractures of both patellas with marked separation of the fragments. At operation, July 24, 1933, nine days after admission,

37. Bertwistle, A. P.: Notes on Fractured Patella, *Lancet* 1:1349 (June 29) 1929.

38. Grubal, quoted by Speed =

40. Steinke, C. R.: Simultaneous Fractures of Both Patellae, *Ann. Surg.* 58:510, 1913.

the upper fragment of the left patella was removed and the fragments of the right patella were drilled longitudinally for the reception of kangaroo tendons and the fragments brought up into apposition. It was felt that this case presented a unique opportunity for testing the efficacy of both the suturing and the excision method. Routine postoperative treatment was carried out relative to the left knee and a walking-iron was incorporated into the cast on the right leg before discharge from the hospital. When examined, May 3, 1935, he had painless motion of both knees and full flexion and extension on the left, 90 degrees flexion and full extension on the right. He went up and down stairs easily and held his body weight on either partly flexed extremity. There was some flexion impairment of the right knee but withal the patient had an excellent result and was well satisfied. Radiographic examination of both knees revealed little of note.

Because fractures of the patella are said not to occur under the age of 20, the following two cases are reported briefly:<sup>41</sup>

CASE 5.—J. K., a white youth, aged 18, fractured the left patella in an automobile accident, and radiographic examination revealed an evulsion type fracture of the lower pole of the left patella with separation of 1 inch (2.5 cm.). At operation, May 3, 1934, some three weeks after admission (the operation was delayed because of the patient's general condition, he having suffered extensive lacerations about the face and the loss of ten teeth), a fragment 2 by 2 cm. was removed from the patellar ligament and the ligament repaired. Routine post-operative care as previously outlined was carried out and when examined, October 27, the patient had full flexion and extension of the affected extremity and he walked up and down stairs normally.

CASE 6.—A. M., a white boy, aged 12 years, fell off a porch, injuring the right knee. Radiographic examination revealed an oblique fracture through the middle of the right patella with slight separation of the fragments. The patient could not raise the right knee off the bed, so injury to the lateral ligaments was suspected and operation was advised. At operation, Dec. 23, 1933, four days after admission, the capsule of the knee joint was found to be intact, and no injury to the patellar capsule was found. The patellar capsule over the fracture site was strengthened with a few interrupted sutures, and a plaster mold was applied. Examination, Oct. 27, 1934, revealed a normal knee function, and the parents were well satisfied.

The study of the method of treating fractured patellas as herein outlined is being continued, and several fresh cases have been treated surgically since Jan. 1, 1935. These have in many instances not been followed for a sufficient length of time, however, to evaluate the end results.

#### CONCLUSIONS

1. A new conception of the treatment of acute fractures of the patella, total and partial excisions of the patella, is productive of excellent clinical results and is justified in the light of the functional anatomy of the knee joint.

2. When the patella is markedly comminuted, subperiosteal excision is done at once. When there is a sizable distal fragment, the proximal fragment is excised. Excision is the simplest procedure when the distal portion is markedly comminuted.

3. The question of nonunion or of fibrous union of the patella or of adhesions to the femur never arises.

4. The operator may choose his incision provided exposure is adequate to investigate and repair the tears in the knee joint capsule.

5. The length of hospitalization in our series was substantially less than that for the series treated by older methods.

6. The patella does not regenerate following excision.

## VESICO-INTESTINAL FISTULAS, CAUSED BY FOREIGN BODIES IN THE BOWEL

ROBERT H. HERBST, M.D.

AND

EDWIN M. MILLER, M.D.

CHICAGO

The number of cases of vesico-intestinal fistulas reported in the literature is considerable, most of the cases being due to diverticulitis and a malignant condition. A fair number are caused by the rupture of an appendicele or pelvic abscess into the bladder with a resultant fistula. Trauma, serious bowel infections, tuberculosis, actinomycosis, syphilis and bilharziasis play a small rôle in the etiology.

Fistulas between the bowel and the bladder caused by foreign bodies in the bowel are quite unusual.

#### REVIEW OF THE LITERATURE

In a review of the literature it has been difficult to cull out these cases, owing to the fact that the cause of the fistula is frequently not stated; also in many of them it has been impossible to determine whether the foreign body that produced the fistula was introduced into the bladder or whether it was ingested. There are quite a number of reports of cases in which the fistulas were produced by bladder calculi ulcerating into the bowel, particularly the rectum. These will not be considered in this discussion. Morrissey, in a comprehensive review of the subject of vesico-intestinal fistulas, states that "the location of the opening in the intestinal canal is most common in the rectum, the next most common in the sigmoid and the least are in the small intestine and cecum."

Kingdon<sup>1</sup> in 1842 reported a fistula between the bowel and the bladder, produced by the passage of a needle from the appendix into the bladder. Autopsy showed that a needle was the nucleus of a large stone.

Roberts<sup>2</sup> reported the case of a man, aged 47, from whom a stone was removed by perineal cystotomy. The nucleus of the stone was found to be a piece of a slate pencil which the patient had swallowed six months previously.

McWhinnie,<sup>3</sup> cited by Cripps, reported the case of an old man, a physician, who for nine years had passed gas and occasional feces from the urethra during urination; no urine was passed from the rectum. In April 1849 he had passed a partridge bone by way of the urethra. He had recurrent attacks of intestinal obstruction and died of ileus and secondary peritonitis in 1862, after an illness of many years. In this case the shape of the bone was not described and it might have been introduced into the bladder and produced the fistula.

Guterbock<sup>4</sup> reported a case of gallstones passed in the urine. He made four lithotripsies and removed 13 Gm. of gallstones. The manner in which they reached the bladder was not stated. He cited the case of Faber and Kostlin: A man, aged 35, passed gallstones in the urine at intervals. He died at the age of 62. The gallbladder was connected with the urachus. Kostlin cited a case of G. Pelletan, whose patient,

2. Roberts, A.: *M. Times & Gaz.*, London 40: 113, 1859.

3. McWhinnie, A. M.: *M. Times & Gaz.*, London 1: 28, 1863.

4. Guterbock: *Gallenstein Konkreme in der Harnblase*, *Virchows Arch. f. path. Anat.* 66: 273, 1876.

aged 26, passed many gallstones in the urine. (Michel, 1909, and McDonald, 1924, also reported finding gallstones in the bladder.)

Fleury<sup>5</sup> described the case of a man with symptoms of vesical stone who was found to have a rectovesical fistula. Gas was passed with the urine. On cystotomy a shoemaker's awl, which was coated with urinary salts, was removed. The awl had been inserted into the bladder fifteen years prior by a companion.

A man, aged 35, with pulmonary tuberculosis, accidentally swallowed a needle 3 cm. long. This passed from the rectum into the bladder so that the head was in the rectum and the point in the bladder. It was coated with phosphatic salts. The patient died of tuberculosis.<sup>6</sup>

Flaubert<sup>7</sup> reported the finding of a bone in the bladder; no details were given.

Harrison<sup>8</sup> reported the case of a man, aged 50, who had had intestinal irritation for several months and had passed feces and gas at each urination for three weeks. A hard tumor the size of a cricket ball was felt in the fundus of the bladder; this proved to be the femur of a rabbit, which had passed from the intestine into the bladder. A bean-sized mass, which was the expanded end of the rabbit's femur, was passed by way of the urethra. He received medical care but the fistula persisted. Harrison also reported the case of a sailor who had symptoms of vesical stone. The whale-bone mouthpiece of a pipe was found in the bladder on cystotomy. The patient stated that the pipe stem had been swallowed a long time before; however, since it still had the odor of tobacco, the patient's veracity might safely be questioned.

Benham<sup>9</sup> reported the case of an insane person who inserted an umbrella rib into the urethra, which passed through the apex of the bladder into the duodenum; the part of the rib that was in the bladder was incrustated. No symptoms appeared for two years, and the patient died of peritonitis. Some of the details of this case are lacking.

Arthur<sup>10</sup> reported the case of a woman, aged 45, who had swallowed a pin eleven years before. Great pain developed in the lower part of the abdomen which lasted for several weeks, and there were blood and feces in the urine. Assisted by her husband, the pin was removed from the urethra. A laparotomy was performed, and since it was impossible to separate the uterus, bladder and bowel, the incision was closed. She showed some improvement.

Keen<sup>11</sup> reported the case of a man, aged 24, who had had dysuria since the age of 7 years, at which time the family doctor had removed a pin from the urethra. There was no history of the swallowing or insertion of a pin. At 23 he was thought to have a rectovesical fistula, secondary to the rupture of a prostatic abscess. Two attempts to close the fistula were unsuccessful. A laparotomy was performed, and a long appendix attached to the bladder wall was found; this was separated from the bladder and removed. The patient made an uneventful recovery.

Rautmann<sup>12</sup> reported the case of a multipara, aged 21, who swallowed a hairpin, which was later found in the bladder. This was removed and the patient was cured. The question arises as to whether she swallowed the hairpin or not.

Von Hacker<sup>13</sup> reported the case of a man, aged 51, who had an aerometer pass from the intestine into the bladder, which was later removed. It had been swallowed by the patient five weeks before. Two years later he swallowed a piece of wood, which was likewise removed from the bladder. Here again is the question of the route of entrance into the bladder.

Paul<sup>14</sup> reported the finding of a long cylindric stone in a bladder, the stone having a sewing needle (1.5 cm. long) as its nucleus. The presumption was that the needle had been swallowed and had ulcerated through the intestine into the bladder. This is also doubtful.

Jacomet<sup>15</sup> reported the finding of a pencil 7.5 cm. long, which had been introduced through the anus, in the bladder of a 12 year old child. The patient had a rectovesical fistula. Suprapubic cystotomy was performed, the bladder drained and the patient cured.

Exner<sup>16</sup> reported the case of a woman, aged 54, who was operated on for tumor of the bladder vertex. An inflammatory mass containing a wood splinter 2 cm. long was found; this had perforated from the intestine into the bladder.

Kapsammer<sup>17</sup> operated on a patient for an incrustated tumor mass and found an incrustated bone. One year later he found an incrustated fecal stone in the same place.

Mirabes<sup>18</sup> reported the case of a patient who put a glass tube into the rectum, which wandered into the bladder. This tube was 15 cm. in length and had been used sixteen months previously and left in the rectum. Symptoms of pain and distress developed in the bladder, and pus and blood appeared in the urine. The tube was removed and the patient was cured.

Parham and Hume<sup>19</sup> in a review of the literature on vesico-intestinal fistulas, reported a case in which a pin had been swallowed eleven years before.

Pakowski<sup>20</sup> reported the case of a woman, aged 36, who complained of pain in the bladder of six months' duration. A calculus was found in the bladder, which had formed around one end of a crochet needle; the needle had been introduced three and one-half years before and had perforated through into the intestine. At operation part of the needle was found in the bladder and part in the intestine. There was no gas or feces passed in the urine. The patient was discharged as cured.

Bond<sup>21</sup> reported the case of a sailor in whom the following articles were found in the bladder: from eighty to ninety nails weighing 350 Gm., 20 Gm. of cobblers' nails and carpet tacks, one roofing nail, several pieces of glass three-fourths inch long and one-half inch in width, bits of stone, enamel from a tooth, a

carpal bone of a small animal and two 3-inch screws. At autopsy there was found a walled off perforation of the ileum in which eight tacks were found. A recent perforation of the sigmoid into the left side of the bladder was also found. The patient stated that he got drunk and swallowed these articles!

Schwarz<sup>22</sup> reported the case of a female who swallowed a pin, which was removed from the bladder. In 1931 he also reported a case of a crochet needle in a bladder, with a secondary perforation.

Lower and Farrell<sup>23</sup> reported the case of a man, aged 26, who had had a stone with a pin nucleus removed from the bladder in 1925. His mother stated that the pin had been swallowed when he was 6 months old. He had had bladder stones for eight years. Cystoscopic examination revealed an opening in the upper part of the bladder. Lower performed a suprapubic operation and the appendix was found adherent to the dome of the bladder; the vesico-intestinal fistula was in all probability due to the pin swallowed by the patient in infancy, which had lodged in the appendix and perforated into the bladder.

Nesbit and Collier<sup>24</sup> reported the case of a girl, aged 13 years, who ten years prior to entrance into the hospital had had a cystotomy with removal of a bladder stone. A vesico-intestinal fistula was also found. Embedded in the stone was a pin which had caused appendicitis, and the appendix had become adherent to the bladder, ruptured into it and formed the fistula.

These two cases, and those reported by Keen and Kingdon, are the only cases of vesico-intestinal fistulas produced by foreign bodies passing from the appendix to the bladder that were found.

In all probability the twenty-eight cases reviewed here do not represent every case of foreign body producing vesico-intestinal fistula, but the review is helpful not only in showing that the condition is uncommon but also in giving one an idea of the various ways in which foreign bodies produce this condition.

#### REPORT OF CASE

To these reported cases we add a somewhat detailed report of a case in the urologic service of the Presbyterian Hospital.

A man, aged 65, for six months prior to admission had been disturbed by frequency and urgency, having to urinate about every hour, day and night. This was associated with severe pain in the lower part of the abdomen and pain in the bladder at the end of urination. He had repeated attacks of chills and fever. The urine was cloudy and often contained blood. He had lost about 35 pounds (16 Kg.) in the past six months. He never had had any roaring in the bladder or escape of gas from the urethra. A large fixed mass, about the size of a grapefruit, could be palpated in the median line above the pubis. The prostate was only moderately enlarged, grade 1, soft, smooth, symmetrical and not fixed. There was no residual urine. The urine was found crowded with pus and blood and on culture grew gram-negative rods and gram-positive cocci, and the plate was overgrown with *Bacillus proteus*. The blood chemistry was normal, the phenolsulfonphthalein output was 87 per cent in two hours, and the Wassermann reaction was negative. A flat plate of the urinary tract showed slight liping of the lumbar spine but otherwise was negative.

A cystogram showed a slightly irregular outline of the bladder and multiple phleboliths. Fluoroscopy of the chest was negative. A barium sulfate enema and fluoroscopy showed that a column of barium entered the rectum and rectosigmoid rapidly. In the middle of the sigmoid a filling defect was seen with a small channel leading from the margin of the intestine, suggesting a fistulous tract. Films confirmed the fluoroscopic observations. Examination of washings from the bladder following the barium enema was negative for barium sulfate.

On cystoscopic examination the bladder was markedly injected throughout. There was only a slight intrusion of the prostate into the bladder. A foreign body was seen lying on the floor of the bladder, which was about 4 cm. in length, 0.5 cm. in width, pointed at one end and black. When grasped with a rongeur forceps pieces broke off, but we finally succeeded in removing it. On examination it was found to be vegetable matter.

A brown spot was seen on the posterior wall of the vertex of the bladder. This was surrounded by an edematous area,

Fig. 1.—Steps in the operative procedure.

and a small depression was seen in the center, the usual appearance of the bladder end of a vesico-intestinal fistula.

Attempts to pass a catheter into the center of this area failed. Sodium iodide solution introduced into the bladder could not be visualized in the intestine.

Before we approached this case surgically we were uncertain as to the nature of the pathologic condition but considered it most likely a carcinoma of the sigmoid colon or a chronic diverticulitis. The loss of 35 pounds and the nodular feel of the large suprapubic mass suggested a malignant growth, but the general well being of the patient, the absence of blood in the stools and the presence in the x-ray film of small diverticula spoke very strongly for a chronic benign process.

June 13, 1934, the abdomen was opened through a left paramedian incision and thoroughly exposed. There was a firm nodular tumor mass the size of a man's two fists involving the sigmoid colon and the dome of the urinary bladder, and firmly adherent to its wall were several loops of small intestine and a large thick-walled appendix. It had the gross appearance and feel of a carcinoma, yet it was not possible to be sure that it was not a diverticulitis, because the liver was smooth and no enlarged glands could be felt in the mesentery. It seemed questionable whether the mass was resectable, but in view of the severe contamination of the urinary tract a clear indication

<sup>22</sup> Schwarz, in discussion on Perlmann, S.: *Ztschr. f. Urol.* 21: 42, 1927.

<sup>23</sup> Lower, W. E., and Farrell, J. I.: *Ann. Surg.* 93: 623 (Feb.) 1931.

<sup>24</sup> Nesbit, R. M., and Collier, F. A.: *Am. J. Surg.* 25: 536-538 (Sept.) 1934.

existed for sidetracking the fecal current above this level. Through a separate muscle-splitting incision, therefore, a left inguinal colostomy was made and the rectus incision closed. Figure 1A illustrates diagrammatically the situation at the close of the first operation.

The patient recovered nicely from this procedure, and his progress was rapid. The colostomy functioned well, the urine cleared rapidly, and his appetite improved steadily. July 30 (six weeks after the first operation) the abdomen was reopened through a right paramedian incision. The adherent loops of intestine were easily separated, and a resection of this large tumor mass was carried out, including with it the appendix and upper third of the bladder. The opening in the bladder was closed with a double row of catgut, the sigmoid colon just distal to the tumor was closed with a purse string, and the resection carried proximally almost up to the colostomy. Figure 1B represents the operative field at the closure of the second procedure. When the specimen was opened after removal, much to our surprise the tumor was found to be made up of a chronic, very thick-walled fistulous tract between

Fig. 2.—Appearance of tumor of sigmoid with communication with the bladder, caused by a chicken bone: A, bone; B, bladder; C, sigmoid colon.

the sigmoid and the bladder, and in this tract lay a large curved, sharp pointed chicken bone (fig. 2). There was no evidence of malignancy and there seems little doubt that a diverticulum had originally been the lodging point for this foreign body. From there it had slowly worked its way into the bladder.

About five weeks later, September 6, the patient was operated on for the third time, the object being to reestablish the continuity of the large intestine and perhaps get rid of the colostomy opening.

Consequently the abdomen was opened again through the original left paramedian incision, which was extended well above the umbilicus. The entire descending colon down to the colostomy and the left half of the transverse colon were mobilized (fig. 1C) by dividing the outer half of the mesentery so as to permit a lateral anastomosis between that part of the descending colon just proximal to the colostomy and the sigmoid colon, which originally lay just distal to the tumor mass. Recovery after this operation was, as after the two previous, uneventful.

On October 1, three and one-half months after the first operation, the final chapter in this interesting clinical drama was written; namely, the closure of the colostomy (fig. 1D).

This involved resection of the entire part of the intestine involved in the colostomy itself and the short stump distal to it and as far proximally as the site of the lateral anastomosis, in order to avoid leaving a fluid pocket at this point.

The end result, as judged by the appearance of the patient one year after his dismissal from the hospital, has been most pleasing both to the surgeons and to the patient himself.

#### COMMENT

In a careful study of the reviewed cases it was very difficult in many instances to determine the origin of the foreign body: (1) whether it traveled by way of the gastro-intestinal tract and for some reason hesitated in a portion of the bowel, (2) whether it became lodged in a diverticulum causing an inflammatory reaction with adhesion to the bladder wall and finally ulcerating through, or (3) whether the foreign body was introduced into the bladder through the urethra and ulcerated through the bladder wall, involving the wall of the intestine and in this way producing a fistula.

Considering the large number of foreign bodies found in the bladder, including stones which cause little or no change in the bladder wall, it is quite evident that the production of a fistula in this way is not very common.

The symptoms of foreign body vesico-intestinal fistulas do not differ very much from those of fistulas due to other causes. In addition to the striking symptoms of passage of gas and feces through the urethra and roaring in the bladder, the frequency, urgency, pain and strangury are more marked in cases presenting a foreign body. Again, these patients are likely to have more aggravated intestinal symptoms, which may precede those of the bladder.

When infection from the bladder spreads to the upper urinary tract, symptoms produced by renal infection appear, chills, fever, pain in the back, and, if the parenchyma becomes involved, the symptoms of renal damage may present themselves.

The presence of urine in the bowel movements is not as common in vesico-intestinal fistulas as some would believe, and it would seem that the intestinal contents, gas and feces, may pass into the bladder without a reverse flow of urine into the intestine. This is shown also by the fact that it is not often possible to visualize the intestine by injecting a contrast fluid into the bladder. The exception to this occurs in those cases in which a severe cystitis has developed with the production of a small thick-walled compensated bladder associated with increased intracystic pressure. This is true also in cases in which the condition is complicated by some form of obstruction of the lower urinary tract. Under these circumstances urine is likely to be found in the bowel movements.

We have been able to visualize the intestine a few times by passing a ureteral catheter into the bladder end of the fistula and injecting sodium iodide.

The preoperative diagnosis of vesico-intestinal fistula with present-day urologic methods is not difficult. The diagnosis of the cases produced by foreign bodies may not offer much difficulty if the foreign body can be found in x-ray films or seen with a cystoscope. In our case this was not possible. The chicken bone that produced the fistula was surrounded by a very large inflammatory mass involving the intestine and failed to show in the x-ray film. The part of the bone that lodged in the wall of the bladder did not protrude into the bladder and could not be seen with a cystoscope.

104 South Michigan Avenue—700 North Michigan Avenue.

COMPRESSION OF THE CAUDA  
EQUINA BY THE LIGA-  
MENTUM FLAVUM

WALTER D. ABBOTT, M.D.

DES MOINES, IOWA

The diagnosis of compression of the lumbosacral roots of the spinal cord following injury is sometimes quite difficult. The usual classic sequence of root pain, loss of motion and sensation, vesical or rectal incontinence and absent reflexes does not prevail in each case. The symptoms of root pain which is accentuated by

lying on the back or on exertion should lead to a suspicion of compression of the cord. Hypertrophy of the ligamentum flavum in the lumbar region has been described on only three occasions.

The case reported by Elsberg,<sup>1</sup> cited the instance of a woman, aged 39, who was thrown from a car ten months prior to her operation. She suffered from stiffness of the back, with pain over the distribution of the fourth lumbar root

Fig. 1.—Defect between the fourth and fifth lumbar vertebrae on the left, indicative of a space-occupying lesion in this region.

on the left side. Roentgenograms revealed an old fracture and thickening of the arches of the fourth and fifth lumbar vertebrae. On performing a laminectomy, he found a thickened ligamentum flavum, lateral and posterior to the dura, which involved the fourth lumbar root. Apparently the ligament had been torn loose. Removal of this ligament was followed by complete recovery.

Towne and Reichert<sup>2</sup> reported two cases of compression of the lumbosacral roots of the spinal cord by thickened ligamenta flava.

One case reported was that of a laborer, aged 50, who may have received minor back injuries; the other was that of a housewife, aged 32, from whom no history of injury was obtainable. In both instances relief of pain was obtained by removal of the thickened ligamenta flava.

## ANATOMY

The ligamenta flava stretch across the posterolateral aspect of the spinal canal between the laminae. The ligaments, composed of yellow elastic tissue, are attached to the anterior aspect of the superior laminae and posterior surface of the inferior. The two ligaments of each interlaminar space fuse in the midline and extend laterally to form the posterior margin of the intervertebral foramina. The ligament, as normally observed during laminectomy, is 1 or 2 mm. thick and yellow.

## REPORT OF CASE

A young woman, aged 23, single, was referred to me, Oct. 29, 1935, because of pain in the left buttock radiating down the distribution of the left sciatic nerve.

In April 1935, in alighting from a car, she tripped and fell, landing on the left buttock and suffering a very severe contusion.

In July she began to complain of a dull backache in the region of the lumbar vertebrae. Roentgenograms of the spine at that time were negative and her family physician made a diagnosis of sacro-iliac strain. She achieved relief from pain by wearing a sacro-iliac belt. However, in August pain began to develop in the left posterior thigh and leg to the heel, occurring particularly at night, so that she was unable to lie on her back or her left side. The pain was also accentuated by coughing, sneezing, straining or stooping. In walking she noted a tendency to shift her weight to the right.

General physical examination was negative, including laboratory tests of the blood and urine.

Neurologic examination, October 29, was essentially negative. The possibility of a cord lesion developing was considered but, in the absence of symptoms, an epidural injection was performed, October 31. After 20 cc. of procaine hydrochloride had been injected into the caudal foramen, the pain was markedly increased. A total of 60 cc. of 1 per cent procaine hydrochloride was injected. She received no benefit and the injection was repeated in a week with no relief from pain. The pain became so severe that the administration of codeine was necessary to obtain relief.

December 16 she complained of a sense of numbness in the left leg. There was no change in sensation but the left patellar reflex was absent. The left achilles reflex was present.

Jan. 29, 1936, the neurologic status remained the same, except that the left achilles reflex was diminished. A spinal puncture and injection of lipoiodine was advised because of the history of

injury, the severe pain and absence of definite neurologic signs. It was felt that the patient had suffered a rupture of the intervertebral disk with a hernia of the nucleus pulposus into the canal.

February 3 she was admitted to Mercy Hospital, and needles were inserted between the twelfth dorsal and first lumbar vertebrae and between the fourth and fifth lumbar vertebrae. Two manometers were attached; the upper manometer registered 9 cm. of water and the lower manometer 6.5 cm. of water. On jugular compression, coughing and straining, fluid in the upper manometer rose to 15 cm. in the lower to 7.5 cm. Specimens of fluid were taken at each level; there was no excess of globulin in

Fig. 2.—Drawing of hypertrophied ligamentum flavum as found at operation.

the upper one but there was an excess of globulin, 2 plus, in the lower one. The Wassermann test of the cerebrospinal fluid was negative. Then 5 cc. of lipoiodine was injected into the canal at the upper level. The patient was tilted on the fluoroscopic table and a narrowing of the lipoiodine was noted as it coursed between the fourth and fifth lumbar vertebrae, with a tendency for the fluid to go to the right. Roentgenograms revealed a defect between the fourth and fifth lumbar vertebrae suggestive of a hernia of the intervertebral disk on the left. A diagnosis of rupture of the intervertebral disk with compression of the cord was made, and laminectomy was advised.

From the Department of Neurosurgery, Mercy Hospital.  
1. Elsberg, C. A.: Experiences in Spinal Surgery, Surg., Gynec. & Obst. 16: 117-132 (Feb.) 1913.  
2. Towne, E. B., and Reichert, F. L.: Compression of the Lumbosacral Roots of the Spinal Cord by Thickened Ligamenta Flava, Ann. Surg. 94: 327-336 (Sept.) 1931.

February 26, under tribrom-ethanol anesthesia, a laminectomy was performed. The spinous processes and laminae of the third, fourth and fifth lumbar vertebrae were removed. There was a mass of hard fibrous material 2 by 2 by 1.5 cm. posterior and lateral to the cord at the level of the fourth lumbar interspace on the left. This compressed the cord and was adherent to the dura. It was noted that the dura below was a dark blue and that it did not pulsate. When this mass was divided it was found that a nerve root was embedded in the mass; it was freed

Fig. 3.—Tissue removed at operation, illustrating groove through which fourth lumbar root ran.

without gross damage to the root. The mass seemed to originate from the lamina of the fourth lumbar vertebra. After removal of this mass the cord pulsated freely and the color was normal.

The dura was opened and the lipiodine that had been injected previously was removed. No pathologic change in the cauda was noted. The dura was closed with continuous silk sutures; the muscles were closed with interrupted catgut sutures, and the skin with dermal reinforced with silkworm-gut sutures. There was no drainage.

The pathologist reported that the tissue removed consisted of yellow elastic and fibrous tissue. Recovery was uneventful and the patient was dismissed sixteen days after operation. There was no weakness of the extremities, sensation was intact, all reflexes were present, and pain was entirely relieved.

March 25 the patient stated that she was driving a car, walking one or two miles daily, had attended a dance without recurrence of pain, and to all appearances had recovered completely.

#### SUMMARY

This case is reported because of the persistence of root pain with a paucity of demonstrable objective changes. However, in the event of progression of symptoms, spinal manometric readings and injections

Fig. 4.—Thickened ligamentum flavum stained with eosin and hematoxylin; reduced from a photomicrograph with a magnification of 100 diameters.

of lipiodine are justified to determine the existence of an underlying pathologic process which may be removed before severe damage to the nerve roots has taken place. This case illustrates the rôle of antecedent trauma in which the ligamentum flavum was torn and, in the reparative process, scar tissue had caused a compression of the cord.

405 Sixth Avenue.

## LATE TOXIC RESULTS, INCLUDING DERMATITIS EXFOLIATIVA, FROM "SLIM" (DINITROPHENOL)

J. M. HITCH, M.D.

AND

W. F. SCHWARTZ, M.D.

CLEVELAND

The pharmacologic actions of the nitrophenols<sup>1</sup> have been known since 1885, when it was found that these compounds possess the property of elevating the metabolic rate in animals. However, the effect of this chemical group on human beings was not generally recognized until the late war. At this time Perkins<sup>2</sup> investigations on munitions workers in France focused attention on its many toxic reactions.

The therapeutic possibilities of these chemicals apparently were not utilized until 1933, when Cutting, Mehrtens and Tainter<sup>3</sup> introduced dinitrophenol as a treatment for some forms of obesity. They were fully aware of the many potential dangers of this drug and in their original series of cases encountered only mild and transient reactions, perhaps because of the conservative dosage and stringent observation.

From the available reports of toxic manifestations to Jan. 1, 1936, it appears that the early reactions, except in the occasional hypersensitive individual, tend to be mild and transient. These familiar reactions include headache, mild chest pains and backache, excessive sweating and feeling of warmth, night sweats, lassitude, nervousness, tachycardia and palpitation, lowering of the blood pressure, vertigo, pharyngitis and otitis media, abdominal pain, derangement of taste, toxic hepatitis with jaundice, maculopapular erythema, urticaria, edema, purpura and extreme pruritus.<sup>4</sup>

Attempts to predetermine individual hypersensitivity to dinitrophenol have been unconvincing.<sup>5</sup> For this reason it is apparently impossible, at present, to foretell a very serious reaction to even a small amount of the drug. In all, seven fatalities from dinitrophenol and one from dinitrocresol have been reported. Two<sup>6</sup> of these were attributed to a definite overdosage, while

four of them<sup>7</sup> occurred in persons who had taken an amount within the "therapeutic range" and perhaps represent allergic responses. The remaining two fatalities<sup>8</sup> can be accounted for by complicating agranulocytosis.

It appears that a moderate amount of this drug must be taken before a neutropenia is produced. However, Hoffman, Butt and Hickey<sup>9</sup> reported a case developing after a total amount of 86 grains (5.6 Gm.) had been taken over a period of only fourteen days. In the remaining five cases<sup>10</sup> the average ingestion of dinitrophenol was 184 grains (12 Gm.) over a period of fifty-eight days.<sup>11</sup>

Thirty cases of polyneuritis can be found officially reported in the literature.<sup>12</sup> This includes a rather large number showing solely, or in combinations, aberrations of taste which have been interpreted as neuritis. Many cases have shown multiple regional involvement, but the feet and legs are the sites of predilection (stocking type seventeen, glove type ten and derangement of taste eight). Owing to the incompleteness of some reports it is impossible to determine the exact time that elapsed between the beginning of the treatment and the appearance of the neuritic symptoms. From those reports in which this factor was recorded it is found that the average time was at least ten weeks and the dosage apparently was well within the "therapeutic range." There was decidedly a wide variation in the duration of the symptoms, but subsidence within from weeks to months was the rule.

Of the many side actions of dinitrophenol, the rapidly developing cataracts have attracted the widest attention. The literature shows definite reports of fourteen bilateral cataracts,<sup>13</sup> and many of the writers mention additional ones of which they have knowledge. The shortest time reported for the appearance of this complication was three months and the longest eighteen months, with an average of nine months from the time the drug was first taken. The smallest total amount of dinitrophenol taken in these cases was 135 grains (9 Gm.) and the largest 1,900 (123.5 Gm.), with an average total dose of approximately 870 grains (56.5 Gm.). No case has shown spontaneous resolution and most have progressed to complete opacity within about three months.

Little emphasis has been given to the possibility that dinitrophenol may be cardiotoxic. Apparently there

are no lasting or significant alterations in pulse rate, blood pressure or cardiac auscultatory manifestations. Electrocardiographic studies on patients under the effects of this drug are few, there being a total of only five such cases in the literature. These were reported by de Châtel and Motika<sup>14</sup> and by MacBryde and Taussig.<sup>15</sup> The five patients thus studied received an acceptable dosage with close observation and yet showed definite alterations of the electrocardiogram in as early as two weeks. Although the period of follow-up was not prolonged, the original changes persisted for as long as ten weeks even after the discontinuance of the drug for a period of two weeks. It is noted by these authors that all the tracings, even those obtained from experimental animals, were quite similar and probably represented a myocardial dysfunction, as evidenced chiefly by alterations in the T wave.

These later and more severe sequelae are well illustrated by a patient who demonstrated a combination of several of them and whose history is here given:

#### REPORT OF CASE

*History.*—Mrs. G. L., a Jewess, aged 33, admitted to the Cleveland City Hospital Nov. 29, 1935, complained of an extremely pruritic generalized skin eruption, which had been present for eight months. The patient stated that before that time she "had never had any skin trouble." For the two weeks prior to the onset of the presenting complaint she had been taking 2 grains (0.13 Gm.) of dinitrophenol<sup>16</sup> daily, 28 grains (1.8 Gm.) in all. Even before she finished taking the dinitrophenol she began to notice a generalized pruritus, and two or three days later several small erythematous patches appeared on the face and back. New lesions continued to appear on various parts of the body and the older ones progressed to become confluent. The family and past histories were irrelevant.

*Physical Examination.*—On admission the patient was fairly toxic but ambulatory. The temperature was 37 C. (98.6 F.), pulse rate 95, respiratory rate 20, and the blood pressure 122 systolic and 80 diastolic. Practically the entire body surface, including the palms, soles and scalp, showed variously shaped, slightly scaly, beefy red, discrete and confluent patches measuring up to about 20 cm. in diameter. Many of the areas were desquamated and quite raw. Very little of the body surface was exempt. No mucous membrane lesions were found. The eyes and ears were normal, and the remainder of the physical examination was essentially negative.

*Hospital Course.*—The eruption continued to spread and within a few weeks became universal. One month after admission the patient developed a severe classic exfoliating dermatitis with redness and edema of the skin, oozing of serum, universal scaling and crusting, and loss of hair and nails with signs of toxicity and fever. Pruritus became very distressing. Moderate edema of the hands and feet was noted. Painful and disabling cutaneous contractures developed in the palms and popliteal and cubital spaces. Despite the use of many and varied soothing antipruritic and antiseptic remedies, practically no modification in the character of the violent skin reaction was effected until the past few weeks, when possibly there has been some slight improvement. The oozing and edema of the skin have subsided somewhat. For about three months following the development of the exfoliating dermatitis the patient had an unexplained spiking temperature between 35.5 and 39.5 C. (95.9 and 103.1 F.), which, since that period, has become normal. The pulse rate remained between 90 and 100 throughout, and the blood pressure did not vary.

On or about the fortieth hospital day she began to complain of difficulty in hearing and of pain and burning sensations in the hands and forearms. Because the remainder of the body was pruritic, the possibility of polyneuritis was considered. A neurologic consultant reported: "So much of the skin tissues

are involved in this violent reaction that the nerve endings must be badly distorted in receptive function. One can only diagnose a polyneuritis by induction. The deafness may be otitic in origin; i. e., a reactive exudation in the middle ear rather than a nerve impairment." These localized paresthesias persisted practically unchanged for about two months, after which they began to subside.

Also on about the fortieth hospital day (nine and one-half months after the ingestion of the dinitrophenol), the patient first noticed a blurring of her vision. Several days later the ophthalmologists saw the patient and diagnosed "bilateral incipient cataracts." They observed the course of this complication and at the time of this report "there has been no evidence of progression in the lens opacities."

General therapy consisted of injections of hypertonic dextrose, sodium dehydrocholate and sodium thiosulfate intravenously. The last has also been given orally. Liver extract was given intramuscularly. The patient has been on a high caloric diet and 5 units of insulin daily for the past three months. The recent slight improvement that the patient has enjoyed cannot be attributed to any one of the foregoing procedures.

**Laboratory Examination.**—Consistent with a dermatitis exfoliativa, a Prausnitz-Küstner test with "Slim" was negative. The Marsh test on a capsule and its contents was negative for arsenic. The icteric index was 5 and 12 on two occasions; the blood cholesterol was 78 mg. per hundred cubic centimeters; two blood sugar determinations were 46 and 64 mg. per hundred

Intense exfoliation and crusting type of dermatitis at the end of ten and one-half months.

cubic centimeters. The blood urea nitrogen was only 7 mg. per hundred cubic centimeters. A urea clearance test was done with no evidence of renal damage; a phenolsulfonphthalein excretion test, however, showed slight retention, 55 per cent after two hours. Repeated urine examinations were negative for albumin and formed elements. Four blood studies were done with no evidence of agranulocytosis or other blood dyscrasia. There was, however, a slight secondary anemia. The basal metabolic rate was only plus 3. Two electrocardiograms at an interval of two weeks (about one year after the ingestion of the dinitrophenol) were somewhat conflicting and showed but little evidence of definite abnormality. In one, however, there was slight evidence of myocardial damage or dysfunction (low voltage QRS, leads 1 and 3; low voltage T, lead 3). The other showed left axis deviation with increased T wave in leads 1 and 2 but very low voltage T in lead 3.

#### COMMENT

Although combinations of toxic reactions to dinitrophenol have often been reported, the marked multiplicity, severity and tardiness of those shown by this case are remarkable. The most striking manifestation that this patient presented was her violent cutaneous reaction. Its appearance and course have been so similar to the exfoliative dermatitis seen following therapy with the arsphenamines that the close basic chemical relationship between that group and dinitrophenol immediately suggests itself. This relationship

has been mentioned several times in the reports of those cases of agranulocytosis developing from dinitrophenol. A careful search of the literature fails to reveal a previous case showing dermatosis of such chronicity or degree of exfoliation as that exhibited by this patient. In view of the frequent occurrence of the early cutaneous reactions to this drug it is surprising that some have not progressed to the type reported here.

When the pain and burning sensations of the hands and forearms first appeared, a definite interpretation could not be made. However, the subsequent course has been such that a final diagnosis of polyneuritis is justified. The manifestations of this late complication seen here vary in no respect from those previously reported.

The temporary deafness from which this woman suffered was due to an exudative otitis media and apparently is of the same nature as that reported by Dintenfuss.<sup>17</sup>

The cataracts observed here are at variance in two major respects with those previously described. In the first place they developed from an unusually small amount of the drug, and in the second place throughout the period of observation they have remained as minimal opacities. The resulting slight visual impairment would probably have escaped the patient's notice had it not been that she was under hospital observation. This suggests the possibility that other persons with a similar degree of impairment have not sought medical aid.

Electrocardiographic studies of the effects of dinitrophenol on the heart are so few that no definite conclusions can be drawn. That myocardial changes do occur and can be demonstrated electrocardiographically is shown by the few existing reports,<sup>18</sup> and that these changes may persist is at least suggested by the case at hand. It is, however, unfortunate that earlier tracings were not made. This interesting evidence of a possible severe and persistent complication from the use of dinitrophenol should be borne in mind and warrant further consideration.

#### SUMMARY

The case here presented shows a multiplicity of severe and persistent reactions, including exfoliating dermatitis thus far not reported, cataracts and polyneuritis following the ingestion of only 28 grains of dinitrophenol over a period of fourteen days.

**Yellow Fever and Geography.**—Yellow fever had a marked effect on the "geographic expansion of the United States." In the latter days of the eighteenth century Napoleon sent a large body of troops under his brother-in-law, General LeClerc, to Santo Domingo and Haiti. It was Napoleon's plan after he had overrun those countries in the West Indies to send his troops on from there and occupy in force the Floridas and the territory of Louisiana on the American continent. However, as a result of yellow fever LeClerc's troops were practically decimated and became so debilitated and reduced in physical and numerical strength that his plans failed and he had to relinquish his intentions regarding the western hemisphere. Therefore in 1803 Napoleon was very glad to sell to the United States the territory of Louisiana known to us as the famous "Louisiana Purchase," whereby our country acquired a region which now comprises fourteen states of the Union. Had Napoleon's plans been successful in Santo Domingo, France probably would have been able to take, occupy and hold the Spanish owned Floridas and continue to possess the Louisiana territory with adequate forces.—Patterson, R. U.: Some Important Contributions to Medical Science by Military Surgeons, J. Oklahoma M. A. 29:157 (May) 1936.

THE CHOICE OF BISMUTH OR MERCURY  
WITH ARSPHENAMINE

IN THE TREATMENT OF EARLY SYPHILIS

A. BENSON CANNON, M.D.

AND

JOYCELIN ROBERTSON, M.D.

NEW YORK

After a quarter century of experience with the arsphenamines, there are still schisms in the ranks of experts over many vital phases of their use in the treatment of syphilis. It is not surprising, then, that the status of bismuth—in use as an antisypilitic only a little over a decade—should not have achieved the fixity of the Decalogue. The physician who declines to depend on the drug salesman for his choice, and who attempts instead to sift the testimony of experienced users of bismuth, will find these divided, like Caesar's Gaul, in partes tres: one, led by the French, who see in bismuth a sort of miracle drug, destined to replace the arsphenamines because equally efficacious but less toxic; a second, who believe that bismuth cannot replace the arsphenamines but that as an adjuvant it has certain advantages over mercury, for which it may be substituted either entirely or in part, and a third who evidently feel about bismuth much as a famous Viennese doctor did about mercury when he pronounced it "a crime against the human race."

The stand of the "Bismuth über alles" exponents is already weakened by the generally admitted increase in the incidence of syphilis in France, where bismuth was almost universally substituted for the arsphenamines during the decade following its introduction in 1921. It was noticeable at the Réunion dermatologique in Strasbourg in June 1930 that even the French speakers differed among themselves in regard to the actual accomplishments of bismuth, several eminent syphilologists challenging the optimistic reports from the Fournier clinic and advocating that an arsphenamine be alternated with bismuth, at least in early syphilis. Those of the opposite extreme, who would ban bismuth at any price, seem to consist mostly of those who, like the French, embraced the new drug with initial enthusiasm as better than arsphenamine and, having found its action considerably short of miraculous, will henceforth have none of it.

Together with the majority of American syphilologists, we take the middle ground: we would by all means make arsphenamine bear the brunt of the attack in early syphilis and use mercury or bismuth as an adjunct. On the question of bismuth versus mercury, however, we have found the literature largely a literature of impressions, with surprisingly few systematic comparisons of the two. It was in an effort to determine at first hand the relative efficacy of the two drugs in the treatment of early syphilis that we decided to study the results achieved with various preparations of each, on groups of hitherto untreated syphilitic patients at the Vanderbilt Clinic. A few patients attending City Hospital also were included in the study.

## PROCEDURE

A certain number of patients admitted with primary or early secondary syphilis were placed immediately on bismuth or mercury preparations for a limited trial

period, so that we might observe their response to these drugs, uncomplicated by the arsphenamine factor. During this time the patient's general improvement, the healing of surface lesions and the disappearance of *Spirochaeta pallida* from the lesions were recorded. All these patients were placed on the standard arsphenamine-bismuth or arsphenamine-mercury treatment as soon as their surface lesions had healed. We also followed the results obtained with patients treated on the standard arsphenamine-bismuth or arsphenamine-mercury plan from the beginning. This combined treatment in both groups of patients was then further evaluated on the basis of (1) the reversal of the Wassermann reaction, (2) the number and type of relapses, (3) the patient's tolerance of the drug, and (4) his clinical and serologic behavior after completing the prescribed treatment.

The standard treatment plan to which we attempt to hold every clinic patient admitted with early syphilis calls for a total of three courses, of ten injections each, of an arsphenamine and three courses of fifteen injections each of a mercury or bismuth preparation throughout the first year. During the first month the arsphenamine and mercury or bismuth courses run concurrently; thereafter they alternate or overlap, so that the patient is continuously under treatment with one or the other, or both. The first six injections of arsphenamine may be given twice weekly and the following four at weekly intervals, or they may be given as often as every other day for six injections and the following four at three, four, five and six day intervals to complete the first course. The second and subsequent courses of arsphenamine are given twice weekly for the first six injections and weekly for the following four. The interval between the first and second courses of arsphenamine should be four weeks, between subsequent courses six weeks.

The first course of fifteen injections of mercury or bismuth is given at four or five day intervals for the first six injections and weekly for the following injections of the course. Both intravenous and intramuscular injections may be given at the same visit, for the convenience of the patient, except that during the first two weeks the patient receives from four to six injections of arsphenamine and only three of mercury or bismuth. Between arsphenamine courses, and while the patient is receiving only mercury or bismuth, he is also given potassium iodide by mouth.

If at the end of the first year the blood Wassermann and spinal fluid reactions are negative and there has been neither serologic nor clinical relapse, the patient is permitted to stop treatment and remain under observation, returning at intervals of three months for blood tests during the second year, and at longer intervals thereafter.

This regimen could not always be followed. The Vanderbilt Clinic is not a free clinic and this department has no Saturday or evening hours, so that many employed patients in the lower income brackets find it difficult or impossible to attend more than once a week over any considerable length of time. A number of cases included in the original investigation were excluded from the final analysis because of irregular attendance or other accidental factors which might have interfered with a fair appraisal of the drugs used. Those included may be understood to be patients with syphilis whose infection was of not more than six months' duration at the time they began treatment and who attended with fair regularity. The study comprises 379 cases in all.

## CHOICE OF BISMUTH PREPARATIONS

The mechanism of action of bismuth compounds in the organism is not yet understood, but it seems to depend chiefly on the amount of bismuth metal that can be introduced without toxic effects. At least no differences in the therapeutic efficacy of bismuth compounds have been noted that cannot be accounted for by the ease with which the bismuth metal is split off and taken up by the organism. Of salts in aqueous solution, only one-fourth or one-fifth as much can be injected at a time, as of compounds suspended in oil. And of the amount injected, it appears to be that fraction in active circulation which is therapeutically effective. But this circulating bismuth is for the most part on its way out of the system by way of urine and feces, a small part probably being held back in various organs and released later. Since the compounds in aqueous solution—because of both the smaller individual dose and the aqueous medium—are absorbed and eliminated very rapidly, injections must be given at intervals of one or two days in order to maintain an adequate concentration of the metal in the blood stream. This drawback is increased by the fact that injections of the salts in aqueous solution are usually painful. On the other hand, bismuth compounds suspended in oil, besides being well tolerated in larger amounts, are absorbed much more slowly and eliminated only gradually, so that even with one injection weekly a fair amount of the bismuth metal remains in circulation. Bismuth in oily solution, introduced more recently, is considered to combine many of the advantages of both the foregoing groups with a minimum of their disadvantages. Its action begins more promptly than that of the oily suspensions. It is absorbed more slowly than the soluble salts and therefore remains in circulation longer than these, but its release is not so slow as to risk accumulating toxic residues at the site of injection. Like the oily suspensions, bismuth in oily solution is relatively painless on injection and is even less apt to form sterile abscesses later on. It was with these considerations in mind that the following preparations of bismuth were selected for use in the overwhelming majority of cases in the Vanderbilt Clinic:

*Sodium Potassium Bismuth Tartrate.*—This is the suspension in olive and almond oils, with butyn, each cubic centimeter containing 50 mg. of metallic bismuth. Of the various bismuth preparations investigated by Cole and his co-workers,<sup>1</sup> the oily suspension of the water-soluble tartrate gave evidence of being absorbed more rapidly than the oily suspension of the insoluble bismuth salicylate but more slowly than the various watery or oily solutions tested, so that one injection a week is sufficient to maintain an active fraction in circulation. The injections are relatively painless, and Raiziss<sup>2</sup> found this to be one of the least toxic of various bismuth preparations tested. The individual dose is usually 1 cc. (50 mg. of metallic bismuth) at the beginning and is increased to 2 cc. after the first few injections, making a total of about 1,350 mg. of bismuth metal in a course of fifteen injections.<sup>3</sup>

1. Sollmann, Torald; Cole, H. N., and Henderson, Katharine I.: Excretion of Bismuth in a Series of Clinical Bismuth Treatments, *Arch. Dermat. & Syph.* 28: 615 (Nov.) 1933.

2. Raiziss, G. W.; Severac, Marie, and Moetsch, J. C.: Toxicity of Various Compounds of Bismuth Used in the Therapy of Syphilis, *J. Chemothérapie* 10: 77 (Jan.) 1934.

3. Manufactured by the Dermatological Research and is not to be confused with the so-called tartrate known as "Trepol," used so extensively in France and found by the Council on Pharmacy and Chemistry of the American Medical Association to be virtually a basic bismuth tartrate containing small amounts of potassium, sodium and calcium salts as impurities, and some uncombined potassium sodium tartrate. See Warren, L. E.: What is the Composition of Bismuth Tartrates Used in the Treatment of Syphilis? *J. A. M. A.* 84: 1067 (April 4) 1925.

*Bismo-Cymol* (N. N. R.).—This is the basic bismuth camphocarboxylate in solution in olive oil, each cubic centimeter containing 50 mg. of metallic bismuth. Its toxicity, investigated by Kolmer,<sup>4</sup> both in animal experiments and in clinical trials, was found to be very low, the maximum tolerated dose being fifteen times the amount of the therapeutically active dose. Raiziss<sup>2</sup> also found this preparation to be less toxic than other oil-soluble preparations of bismuth. The initial dose of 1 cc., representing 50 mg. of metallic bismuth, is increased after a few injections to 2 cc., giving the patient a total of about 1,350 mg. of bismuth metal per course, as in the case of the tartrate.

A few patients in City Hospital who were treated with biliposol (N. N. R.) and a few Vanderbilt Clinic patients who received potassium bismuth tartrate (N. N. R.) were also considered eligible for inclusion in the present study. The same dosage scheme was followed for these preparations as for those already discussed (from 1 to 2 cc. weekly). Biliposol, an oil-soluble preparation containing 40 mg. of elemental bismuth in 1 cc., would provide about 1,080 mg. of bismuth per course of fifteen injections. The excessive cost of this otherwise satisfactory preparation has interfered with its wider trial in the two clinics. The potassium bismuth tartrate in suspension in almond oil contains 33.5 mg. of elemental bismuth in 1 cc. and would supply a total of from 900 to 1,000 mg. of bismuth per course. This preparation was replaced by the sodium potassium bismuth tartrate largely on account of the higher bismuth content of the latter product. Any patients who had difficulty in tolerating injections of the oil-suspended salts could usually tolerate the oil-soluble bismo-cymol.

## CHOICE OF MERCURY PREPARATIONS

The same general considerations that have been set forth briefly with regard to bismuth apply also to the choice of mercury preparations, except that the metal content of the various mercurials is subordinate to factors making for tolerance, because of the narrower margin of safety between the therapeutic and toxic doses.

Mercuric salicylate, given in the great majority of cases in the present study, has been used so widely and over so long a period that it would be superfluous to review its claims here were it not for the recent tendency of some syphilologists to demote it in favor of the water-soluble succinimide. Mercuric salicylate, or, more accurately, the basic mercuric anhydride of salicylic acid, contains about 55 per cent of metallic mercury and is relatively painless when injected intramuscularly in a suspension of a vegetable oil. Absorption begins promptly, as shown by comparatively high excretion curves within twenty-four hours after injection,<sup>5</sup> but excretion continues more slowly for a considerable period after the end of a course, thus providing an advantage over the soluble mercurials similar to that of the insoluble salts of bismuth. Weekly injections, beginning with one-half grain (0.03 Gm.) and increasing to 1 grain (0.065 Gm.), keeps a fair amount of the metal in circulation, as evidenced by excretion, and if courses are alternated either with an arsphenamine or a bismuth preparation, toxic symptoms are relatively infrequent.

4. Kolmer, J. A.: Basic Bismuth Campho-Carboxylate (Bismo-Cymol) in the Treatment of Syphilis, *Am. J. Syph.* 15: 190 (April) 1931.

5. Lomholt, S., also Bürgi, E.: *Handb. d. Haut- u. Geschlechtskr.* 18: 1, 1928.

Mercuric succinimide (N. N. R.), the mercuric salt of succinic acidimide, containing approximately 50 per cent of mercury, has proved a worthy addition to the list of soluble mercurials. Like other soluble preparations, it is painful on injection and is absorbed so rapidly that daily injections are needed in order to maintain an adequate concentration in the blood stream. These drawbacks render it impracticable for routine clinic use, but it is valuable in cases in which prompt action is important and the arsphenamines are contraindicated. For patients included in this study, the standard dose was one-fourth grain (0.016 Gm.) given daily or on alternate days.

#### BISMUTH AND MERCURY AS SPIROCHETICIDES

It is doubtful whether either mercury or bismuth exerts direct spirocheticidal action in the system. In vitro, bismuth does not kill *Spirochaeta pallida* even when mixed with serum, but with extracts of certain organs, especially liver, it forms a compound known theoretically as "bismoxyl," which is spirocheticidal. Kolle's experiments indicate that bismuth inhibits the growth of the parasite without destroying it. As for mercury, Lomholt has shown that *Spirochaeta pallida* could grow in a concentration of mercury in the blood serum more than twice as great as that prevailing in the blood of a patient at the saturation point, or limit of tolerance at which toxic symptoms appear. These and other facts suggest that whatever spirocheticidal action is exerted by mercury, and to a certain extent that exerted by bismuth, is indirect, by stimulating the tissues to a stronger defense reaction. Since for a direct attack on *Spirochaeta pallida* we depend primarily on the arsphenamines, the performance of the heavy metals in this respect is of secondary importance. Nevertheless, because the disappearance of spirochetes from open lesions furnishes one of the few visible criteria of a drug's action, we made systematic darkfield examinations from fifty-two cases of primary syphilis. Half the patients in this group received mercury and the other half bismuth preparations. None received any arsphenamine during this test period.

In eleven of the fifty-two cases, *Spirochaeta pallida* could not be found in the chancre fluid, usually because the patient had already used a local disinfectant. In two instances positive gland punctures were obtained where the chancre fluid had been negative. The procedure regularly followed was to make three preparations at each visit, and a "negative" was reported only after all three preparations had proved negative on at least two successive visits. Up to fifty fields were examined on each preparation, depending on the scarcity of organisms.

Among the bismuth-treated cases with positive darkfield before beginning treatment, *Spirochaeta pallida* disappeared

After 1 injection in 1 to 7 days in 12 cases.  
After 2 injections in 3 to 13 days in 7 cases.  
After 3 injections in 11 to 18 days in 2 cases.

In one additional case treated with bismo-cymol, spirochetes were still present after three injections, thirteen days after treatment was begun.

Among the mercury-treated cases, *Spirochaeta pallida* disappeared

After 1 injection in 2 to 5 days in 4 cases.  
After 2 injections in 4 to 11 days in 12 cases.  
After 3 injections in 9 days in 1 case.  
After 4 injections in 8 days in 1 case.  
After 5 injections in 6 days in 1 case.  
After 7 injections in 31 days in 1 case.

Superficially, the results indicate a superiority of bismuth over mercury as a spirocheticide, since 86 per cent of the bismuth-treated patients as against 80 per cent of the mercury-treated patients had negative darkfields after one or two injections of the drug; or, stated in terms of days, one might expect to find a negative darkfield by the fifth day from the average bismuth-treated patient, but not until the eighth day from the average patient under mercury. Allowance should be made, however, for the fact that the four patients who received the succinimide would perforce show a larger number of injections, as this drug was given at shorter intervals than the salicylate. Spirochetes were found in the chancres of some patients from both the bismuth and mercury groups up to the healing of the lesions, and in both groups there were instances in which spirochetes were found in abundance after the lesion had completely epithelized, when the surface was scraped and fresh serum obtained from beneath.

In the preparations from treated patients were observed many atypical forms of *Spirochaeta pallida*—branched, budding and fissured forms interpreted by some investigators, notably Noguchi, as regression forms, by others as organisms in process of active multiplication. In every such case the original preparations made before the patient had received any treatment had shown typical *Spirochaeta pallida* from the same lesion. One case presented two penile chancres, one with a moist necrotic surface abounding in typical *Spirochaeta pallida*, the second with a healed surface and button-like induration showing the atypical forms after the lesion had been scraped and fluid collected on the slide.

#### THE COMPARATIVE VALUE OF BISMUTH AND MERCURY AS JUDGED BY THE HEALING OF PRIMARY LESIONS

Of patients admitted with primary syphilis, sixty-eight were found whose records showed regular treatment (not less than once a week) either with bismuth or mercury preparations alone or with the combined bismuth-arsphenamine or mercury-arsphenamine treatment. The effect of this treatment on the healing of primary lesions has been summarized in table 1. From this it will be seen that among the patients who received only mercury or bismuth preparations from the beginning there was less than a day's difference in the average time required for the primary lesion to heal: 15.8 days for the eighteen patients treated with bismuth preparations alone, and 16.6 days for the twenty who received only mercurials. Thirty-one days was the longest time required for either group. There was no appreciable difference in the time of healing for patients who received the sodium potassium bismuth tartrate and those who received biliposol. Bismo-cymol was not represented in this group. In the majority of cases, the chancre healed after the third injection, the average for the bismuth group being 3.5 injections, representing an average of 0.234 Gm. of bismuth metal. In the mercury group the average time of healing was exactly the same for patients who received the insoluble mercuric salicylate and those who were given the soluble succinimide, but the latter were obliged to have nearly three times as many injections as the former to secure similar results—an average of nine injections of the succinimide as against 3.6 injections of the salicylate.

Among the patients who received bismuth-arsphenamine treatment from the beginning, the chancres

healed in an average of eighteen days, while the average for the corresponding mercury-arsphenamine group was 20.8 days. Or, to judge from the time average of 16.9 days for all thirty-six bismuth-treated primaries, as compared with 18.2 days for the thirty-two mercury-treated ones, a primary lesion might be expected to heal from one to three days sooner under bismuth than under mercury, whether or not the patient received any arsphenamine in the meantime. Curiously enough, the time of healing averages several days less for patients treated with mercury or bismuth alone than for those who received some concomitant arsphenamine treatment. This advantage however is more apparent than

itself. It should be understood, of course, that with clinic patients the time recorded for the healing of lesions is often several days longer than the actual time, since the patient as a rule would not be seen by his physician after the "healing" injection until he returned for the next injection scheduled.

THE HEALING OF SECONDARY LESIONS

The healing of secondary lesions was studied from the records of 180 patients admitted with florid secondary manifestations and treated regularly either with mercury or bismuth preparations alone or with an arsphenamine in addition to mercury or bismuth.

\* The majority of the bismuth-arsphenamine patients and all the mercury-arsphenamine patients received silver arsphenamine for their arsphenamine.

real, because it happens that the overwhelming majority of patients in this particular primary group who were placed on the standard arsphenamine-bismuth or arsphenamine-mercury plan from the beginning were given silver arsphenamine, and some of them had received as many as five or six injections of this preparation before the intramuscular injections were begun. Since this time, silver arsphenamine has demonstrated itself to be much slower in action than arsphenamine. One of our previous studies<sup>6</sup> showed that ordinary primary lesions of patients treated with arsphenamine and either bismuth or mercury as an adjunct will heal in an average of nine or ten days; more recent cases, in which slightly smaller doses were given, averaged 12.5 days (table 2). Either of these represents a much

If the relative efficacy of bismuth and mercury alone on all types of secondary lesions (table 3) is considered first, results indicate a slight advantage for mercury, since the average time of healing for the forty-five patients treated with mercury preparations was 20.8 days, as compared with 22.2 days for the fifty patients treated with bismuth preparations. The time average was identical for the patients who received mercuric salicylate and those who received the succinimide, but the latter were obliged to have between two and three times as many injections in order to achieve the same results. The majority of the patients in the bismuth group received sodium potassium bismuth tartrate and the group averaged 0.292 Gm. of bismuth metal before secondary lesions were entirely healed.

With regard to the number of injections, mercury shows itself prompter but more uneven in its action than bismuth. Considering only the cases treated with the salicylate, and remembering that two or three times as many injections of the succinimide would be required, one finds that very nearly half the thirty-seven mercury-treated patients had their lesions healed by the time they had received three injections, whereas less than one third of the fifty bismuth-treated patients were free from manifestations after three injections. After five injections, 81 per cent of the mercury-treated patients were lesion free, as compared with only 66 per cent of the bismuth-treated ones. However, after a sixth injection all but four of the bismuth group had cleared, the slowest requiring eight injections, while seven of the mercury group still remained, the slowest of these requiring eleven injections to clear entirely. In addition, there were two cases which responded so poorly to mercury that the patients were placed on arsphenamine treatment before the lesions had healed.

When an arsphenamine was given along with a mercury preparation from the beginning (thirty-four cases), the time for the healing of secondary manifestations averaged slightly less than it did under the bismuth-arsphenamine plan (fifty-one cases) but the difference was negligible: twenty days for the mercury-arsphenamine group and 20.7 days for the bismuth-arsphenamine group. Mercuric salicylate and bismo-cymol were the only preparations given intramuscularly in these groups, while arsphenamine, silver

\* Practically all patients received some bismuth or mercury besides the arsphenamine.

shorter time than that required for bismuth or mercury alone or for a combination of either with silver arsphenamine.

Although the "bismuth alone" group received preponderantly sodium potassium bismuth tartrate, and the "bismuth-arsphenamine" group preponderantly bismo-cymol, both bismuth groups received almost identical average amounts of bismuth metal (0.234 and 0.25 Gm. respectively), the slight advantage being with the bismuth-arsphenamine group. The "mercury alone" and "mercury-arsphenamine" groups, both of whom received a majority of their intramuscular injections in the form of mercuric salicylate, show a greater difference in the time of healing (16.6 days vs. 20.8 days) than do the two bismuth groups (15.8 days vs. 18 days), so that the apparent disadvantage of using an arsphenamine seems to lie in the choice of the arsphenamine

C. Cannon, A. B., and Karelitz, M. B.: The Comparative Value of the Arsphenamines in the Treatment of Early Syphilis, J. A. M. A. 97: 1523 (Nov. 21) 1931.

arsphenamine and neoarsphenamine were all represented, silver arsphenamine preponderating in both groups.

If all the bismuth-treated secondaries are combined in one group and all the mercury-treated secondaries in another, both those patients who received some arsphenamine and those who did not, there remains an advantage of one day, on the average, in favor of mercury (20.4 days as against 21.4 days for bismuth). A glance at the figures comparing the different arsphenamine preparations among themselves will show that either arsphenamine or silver arsphenamine, in combination with intramuscular injections, acts more promptly than mercury or bismuth alone, but that even mercury or bismuth alone is more effective than a combination with neoarsphenamine, which gives the slowest response of all (an average of 23.7 days for forty-eight cases).

Looking back over the aggregate results obtained with preparations of bismuth and mercury, either alone or in combination with an arsphenamine, in the healing of primary and secondary lesions, it might be inferred that in the primary stage, before the body has developed its own defense mechanism, bismuth is more effective than mercury—possibly by virtue of its spirocheticidal properties; whereas by the time the body has elaborated

five injections of mercuric salicylate, twenty-three days after beginning treatment) and no essential difference was noted in the serologic behavior of the two groups thereafter, this factor will be ignored in presenting the results in the primary cases.

with a heavy metal, as would usually be done in practice, arsphenamine will give the best results, and the advantage of either heavy metal over the other shrinks to minor proportions.

THE COMPARATIVE VALUE OF BISMUTH AND  
MERCURY IN REDUCING A POSITIVE  
WASSERMANN REACTION

The comparative value of bismuth and mercury in reducing a positive Wassermann reaction was perforce evaluated on the basis of the combined bismuth-arsphenamine and mercury-arsphenamine treatment, except that the limited number of patients aforementioned received a partial course of the intramuscular injections before beginning their first arsphenamine course, whereas the majority were started at once on the combined treatment. Since only one seropositive primary patient had a reversal of the Wassermann reaction under the intramuscular treatment alone (after

reaction became negative, receiving an arsphenamine and various amounts of mercury or bismuth. The fifteen who received bismuth preparations (sodium potassium bismuth tartrate and bismo-cymol) required an average of 65.4 days to become Wassermann negative, while twenty mercury-treated patients (all of whom received mercuric salicylate) became Wassermann negative in an average of 61.8 days, one patient treated with mercuric salicylate and silver arsphenamine remaining positive throughout nine months of fairly regular treatment and then showing fluctuating serologic reactions for an additional two years. Of twenty-six patients admitted in the seronegative primary stage, eleven, or about 40 per cent, became seropositive within a few weeks after beginning treatment and then reverted to negative as treatment was continued. This occurred in about equal proportions in both mercury and bismuth groups, and among those who received an arsphenamine from the beginning as well as those who were started on bismuth or mercury alone.

Besides these transitory positives occurring in patients who began their treatment in the seronegative stage, there were two early serologic relapses among regularly treated primaries in the mercury group and one in the bismuth group. Not one of the three was strongly positive, and all later reverted to negative. A number of patients showed a positive Wassermann reaction after absentsing themselves from the clinic for various lengths of time, but it would be obviously unfair to consider these cases as indicative of the efficacy or inefficacy of the drugs used.

If the serologic response of the patients who began their treatment before secondary manifestations had

appeared are balanced, it might be concluded that those who receive mercury in addition to an arsphenamine have a slight advantage over those who receive bismuth, in that a positive Wassermann reaction became negative in the mercury group about four days earlier, on the average, than in the bismuth group. But one patient treated with mercury would probably be classed as Wassermann fast, and the proportion of serologic relapses was slightly higher in the mercury group, although the number of cases is too small for this to be of much significance.

*In Secondary Syphilis.*—All patients discussed here were admitted with florid secondary manifestations and a strongly positive Wassermann reaction. Altogether 158 were considered eligible for comparative study,

the mercury-treated cases and only one of the bismuth-treated cases remained positive for over six months. These persistent positives were not included in computing the averages.

Considering next the 108 patients who had the typical combined treatment from the beginning, one half receiving bismuth and arsphenamine, the other half mercury and arsphenamine, we find that all but two in the bismuth-arsphenamine group became Wassermann negative in an average of 79.9 days from the time of beginning treatment, while the patients in the corresponding mercury-arsphenamine group required 82.6 days. The two remaining bismuth-arsphenamine cases and five mercury-arsphenamine cases remained positive for over six months of regular treatment.

having been treated regularly at least until their Wassermann reaction became negative, or, in the Wassermann-resistant cases, for not less than six months. The majority were under treatment and observation for one year or longer. The serologic results were evaluated on the basis of the combined bismuth-arsphenamine and mercury-arsphenamine treatment, except that slightly less than one third of the patients received a partial course of bismuth or mercury before beginning their first arsphenamine course, while the majority received the combined treatment from the beginning. In the belief that it might be of interest to

Taking all bismuth-treated secondaries under consideration here (eighty cases) and all mercury-treated secondaries (seventy-seven cases), the mercury group still requires an average of 85.4 days to achieve a negative Wassermann reaction, while the bismuth group requires only 81.1 days. In addition, there are more than twice as many persistently positive Wassermann reactions among the mercury-treated cases as among the bismuth-treated ones. As might be expected, those patients who received an arsphenamine from the start, in addition to a heavy metal, fared better than did the ones who received only bismuth or mercury until their surface lesions had healed. Arsphenamine, silver arsphenamine and neoarsphenamine are represented in both groups, but it so happens that the mercury-arsphenamine group contained a larger proportion of patients treated with neoarsphenamine than did the bismuth-arsphenamine group. As may be seen from table 7, neoarsphenamine makes the poorest showing of all the arsphenamines in reducing a positive Wassermann reaction in secondary syphilis, so that one may reasonably surmise that mercury if given in conjunction with a more active arsphenamine—preferably arsphenamine—would show itself to be more nearly equal in potency to bismuth.

TABLE 7.—The Comparative Value of the Arsphenamines in Reducing a Positive Wassermann Reaction in Secondary Syphilis

All received bismuth and/or mercury in addition to the arsphenamine.

see whether this difference affected the outcome, we recorded the results separately for the different groups. If first the patients who began their treatment on the heavy metals alone are examined, twenty-six receiving bismuth preparations and twenty-three mercurials, the results as summarized in table 6 disclose a decided advantage for bismuth over mercury, in that the time necessary to secure a negative Wassermann reaction averaged 83.4 days for the bismuth group, as against 92.3 days for the mercury group. Moreover, three of

SEROLOGICALLY RESISTANT AND RELAPSING CASES,  
BOTH PRIMARY AND SECONDARY, UNDER  
REGULAR TREATMENT

Besides those secondary cases in which the Wassermann reaction remained persistently positive throughout six months or more of regular treatment (eight cases under mercury and three under bismuth), there were some which reverted to a weak positive after having become negative and while the patients were still under regular treatment. The distribution of these cases may

be seen in table 6. Of the secondary patients who began their treatment on mercury or bismuth alone, three reverted temporarily to a positive serologic reaction while under active treatment with bismuth preparations, but only one relapsed while under active treatment with mercury. Among the much larger number of patients who were given the combined treatment from the beginning, the groups being evenly divided between bismuth and mercury, there were six relapsing Wassermann reactions among the bismuth-arsphenamine cases and five among the mercury-arsphenamine ones. For the sake of completeness it will be well to add to the picture those patients who failed to respond adequately to treatment begun in the seropositive primary stage: one Wassermann-resistant case and two serologic relapses under regular treatment with mercuric salicylate and silver arsphenamine, and one serologic relapse under bismo-cymol and silver arsphenamine. This makes a total of thirteen bismuth-treated patients, or 13.7 per cent, and seventeen mercury-treated patients, or 17.2 per cent, who failed to show an entirely satisfactory serologic response to early regular treatment. This disregards patients admitted in the seronegative primary stage, among whom occurred a number of transitory positives within a few days or a few weeks after treatment was begun; these are always open to suspicion as having been on the verge of becoming seropositive when treatment was initiated, in which case the first injection or injections evidently act as a provocative. Late-recurrences, appearing after the completion of a year or more of treatment, will be considered under "End Results."

The early relapsing Wassermann reactions enumerated here in all but a single instance were of the  $\pm$  grade (cholesterinized antigen 2+, alcoholic antigen negative, Kahn negative), and reverted to negative as the treatment was continued. How much significance attaches to these temporarily recurrent positives, it is difficult to say: they may represent only the vagaries of a highly sensitive cholesterinized antigen, but until more is known regarding this factor, it was deemed best to report the reactions as they were. For some, at least, of the persistently positive Wassermann reactions it is probable that insufficient dosage is responsible. At any rate these patients were found to have averaged about 20 mg. less of bismuth metal per week and from 15 to 20 mg. less of mercury salts per week than did those patients whose Wassermann reaction became negative within the usual time.

#### END RESULTS

So far we have considered chiefly the response of the various treatment groups to early treatment. It is now necessary to see what proportion of these patients remained symptom free after having completed the minimum amount of treatment considered adequate to prevent a relapse; namely, one year of regular treatment with an arsphenamine and a heavy metal in alternating and/or overlapping courses. One should remember that in separating out the eligibles from the ineligible it was necessary to eliminate not only patients who had attended irregularly or for an inadequate length of time but also those who had been adequately treated for the required year or more, if for any reason more than one heavy metal had been administered during this time. Thus, in a considerable number of cases, mercury and bismuth courses were alternated, either because a patient manifested some symptoms of

intolerance to one drug or because the attending physician wished to avoid such a contingency. There is also the theoretical possibility of the parasite becoming mercury fast or bismuth fast, when one or the other drug is continued over long periods.

Among the sixty-seven cases finally included as eligible for comparing end results, the distribution of favorable and unfavorable outcomes may be seen in table 8. The only patient of this number who manifested a clinical relapse returned to the clinic with generalized serpiginous lesions and a strongly positive Wassermann reaction ten months after having completed a first year of regular treatment, during which time he had received twenty-six intravenous injections of silver arsphenamine and thirty intramuscular injections of bismo-cymol, a total considerably below the optimum recommended.

A study of serologic relapse occurring after one year of regular treatment reveals five recurrences in the bismuth group and four in the mercury group, three of each reverting later to negative, with or without further treatment. As was pointed out in connection with serologic relapses occurring during early treatment, the significance of this phenomenon is the more difficult to

TABLE 8.—Results of Bismuth and Mercury Compared, in Patients Treated Regularly for One Year or More

	Total Number of Patients Treated Regularly for 1 Year or Longer*	Unsatisfactory Behavior After One Year or More of Regular Treatment			Summary	
		Clinical Relapse	Serologic Relapse	Wassermann Fast	Satisfactory	Unsatisfactory
Bismuth	26	1	5†	0	20 77%	6 23%
Mercury	41	0	4†	2	35 85.4%	6 14.6%

\* Includes only patients treated with a single heavy metal throughout.  
† Three later reverted to negative.

evaluate, in view of the fact that more than half these recurrent positives were of the doubtful variety and reverted to negative without further treatment. Two additional cases, however, both treated with mercuric salicylate and silver arsphenamine, remained Wassermann fast, one of them fluctuating between  $\pm$  and negative for nearly three years.

Tests of the spinal fluid revealed a number of positives among patients with early syphilis as yet untreated or only partially treated, all becoming negative under further treatment; but only one patient showed a positive spinal fluid after completing one year of regular treatment. This patient, a woman of 58 admitted with florid secondaries, through an excess of caution was given only one-half the regulation dosage of silver arsphenamine and mercuric salicylate. Her blood Wassermann reaction also reverted to positive and the case is among those already recorded under serologic relapse. At the time of writing, eleven months later, the patient is under treatment and still free from any clinical symptoms of neurosyphilis.

If all these recurrent manifestations are counted at their face value in order to balance the respective achievements of the mercury-arsphenamine and bismuth-arsphenamine treatment, we are left with six cases in each group which showed unsatisfactory behavior after one year of regular treatment. Since the mercury-arsphenamine group is the larger, the

proportion of unsatisfactory outcomes is smaller in this group, and its percentage of satisfactory outcomes is 85.4 as against 77 for the bismuth-arsphenamine group.

#### COMPLICATIONS DUE TO MERCURY OR BISMUTH

A bird's-eye view of the complications due to bismuth or mercury alone and those in which the heavy metals may have been a contributory factor is represented in table 9. The records of all patients in the present study were taken into account for this purpose. Immediate reactions traceable unequivocally to an arsphenamine were of course excluded. Complaints of "sore hip" without objective signs, while given due consideration, were not tabulated under local reactions.

There was no serious reaction attributed to bismuth alone in the entire series, and only one patient had a local reaction at the site of injection. This was a case of purpura which developed around the site of injection of bismo-cymol and attained a diameter of about 8 cm. It was in all probability due to the accidental rupture of a blood vessel, complicated by toxic properties of the drug. The most common by-effects attendant on the administration of bismuth preparations were stomatitis, gingivitis and the "bismuth line" along the gums. These occurred at different stages of treatment in different patients and irrespective of the preparation used. One

In fixing the blame for delayed reactions such as dermatitis, jaundice and neuritis, one can only infer from their relative frequency in the two treatment groups which of the heavy metals makes the less favorable combination with an arsphenamine, since all patients sooner or later had the combined treatment. There are almost twice as many cases of dermatitis and jaundice among patients treated with bismuth and an arsphenamine as among those who received mercury and an arsphenamine, although no dermatitis case in either group was of the severe exfoliative variety. In the literature, both dermatitis and jaundice have been reported in considerable numbers in patients treated with bismuth alone, whereas dermatitis following the internal use of mercury has been a rarity in modern times. Jaundice is not even mentioned in connection with mercury in the leading textbooks, and it is well known that the kidney, rather than the liver, is the organ most susceptible to mercury. The picture is often obscured by the physician's tendency to attribute to the arsphenamine all skin manifestations occurring under combined treatment. Thus in several such instances, when a dermatitis appeared, the physician discontinued the arsphenamine and gave the patient a series of sodium thiosulfate injections, while continuing the bismuth therapy. The rash persisted unchanged

TABLE 9.—Complications

	Attributed to Bismuth or Mercury Alone				Bismuth or Mercury Possibly Contributory

Mercury 199 cases	9 cases	.....	4 cases	5 cases	18 cases 9%	5 cases	1 case	9 cases	.....
									Total
									24 cases 13%
									15 cases 7.5%

patient also complained on three occasions of general lassitude and somnolence lasting for several days, with some elevation of temperature, after injections of bismo-cymol.

Three patients had fairly severe general reactions within a few hours after an injection of mercuric salicylate. One of these reported a temperature of 100.4 F., general malaise, chills, profuse sweating and diarrhea lasting two days, after a first injection of mercuric salicylate (three-fourths grain, or 0.05 Gm.). The next dose, cut to one-half grain (0.03 Gm.), was tolerated without mishap, as were subsequent doses of three-fourths and 1 grain (0.05 and 0.065 Gm.). A second patient, a strong healthy man, aged 38, reported a syncope followed by profuse perspiration a few hours after his third injection (one-half grain, or 0.03 Gm.) of mercuric salicylate. The third patient had chills, fever, congestion of the lungs, and a local swelling of the hip within a few hours after his twentieth injection (1 grain, or 0.065 Gm.) of mercuric salicylate. Not one of the three was receiving arsphenamine at the time. The symptoms in the third case suggest the entry of the needle into a vein, in which case the fault lies in the technic rather than in the drug. Two more patients reported fever and general malaise after several early injections of mercuric salicylate. Besides these general reactions there were more cases of stomatitis and also more local disturbances at the site of injection under mercury than under bismuth preparations, and they occurred as a rule much earlier in the course than did similar reactions to bismuth.

over uncommonly long periods, and one case of jaundice attributed to the arsphenamine persisted for four and one-half months while the patient continued his bismuth injections. The one case of neuritis in the entire series grew markedly worse when two injections of bismuth were given after the patient had complained of pains in the arms and legs and stiffness in the joints. Two cases of generalized pruritus without objective symptoms, one under mercury and one under bismuth medication, were the only other ill effects noted. No patient showed any evidence of nephritis or any significant changes in the blood counts, although a routine urinalysis was done at monthly intervals, and a blood count was made early and late in the courses of treatment. There were no hemorrhages of skin or mucous membranes other than the one case of traumatic purpura already mentioned.

#### SUMMARY AND CONCLUSIONS

On the basis of our observations as a whole, neither bismuth nor mercury appears to have such a decided advantage over the other as much strongly partisan testimony would lead one to believe. While in our comparative studies of the arsphenamines, arsphenamine proved to be almost uniformly superior to neo-arsphenamine, and silver arsphenamine, by every criterion applied, no such clear-cut superiority could be discerned in the performance of either of the heavy metals. Spirochetes disappeared from primary lesions and the lesions themselves healed more promptly under bismuth than under mercury, but a positive Wasser-

mann reaction reversed earlier under mercury in the primary stage; in fact, one primary patient achieved a negative Wassermann reaction in twenty-three days under mercuric salicylate alone (five injections) while his chancre was still unhealed and spirochetes were still present in the chancre fluid. In secondary syphilis, however, the situation was reversed: mercury gave slightly better results than bismuth in the healing of eruptions, condylomas and mucous patches, but mercury-treated cases were considerably slower in becoming Wassermann negative (they were at a disadvantage, however, in that the patients received preponderantly neoarsphenamine for their arsphenamine). Again, there were more than twice as many patients serologically resistant to mercury as to bismuth, but more relapses occurred under bismuth.

Among patients with early syphilis who completed the required first year of regular treatment, there was a larger proportion of satisfactory outcomes in the mercury group than in the bismuth group. The only clinical relapse occurred in a patient treated with bismo-cymol and silver arsphenamine, but the total number of injections received was below the optimum recommended. The only patient who showed a positive spinal fluid after completing a year of regular treatment received mercuric salicylate, silver arsphenamine and arsphenamine in but half the recommended dosage.

In the matter of complications that could be definitely attributed to the heavy metals alone, bismuth was responsible for only half as many as mercury; while of delayed systemic reactions such as dermatitis, jaundice and neuritis, in which both the arsphenamine and the heavy metal may be presumed to have had a part, the mercury group contributed only a little more than half as many cases as the bismuth group.

Thus the differences are not easily weighed and measured, and such differences as appear when the intramuscular injections are given alone, or preceding the first arsphenamine course, tend to become obliterated when an active arsphenamine preparation accompanies the heavy metal from the start. The facts uncovered in the present study suggest that:

1. The salts of both metals have an important place in the antisyphilitic armamentarium. The various preparations selected—both of bismuth and of mercury—appear to have justified themselves in all cases examined in which the treatment was regular and the dosage adequate; but neither metal can compensate for the disadvantage of using an inferior arsphenamine preparation.

2. Mercury gives more brilliant but less uniform results than bismuth, so that in robust patients with a healthy excretory mechanism the body's natural defenses are perhaps more effectively stimulated by the mercurials. For patients less vigorous and for those who do not respond well to mercury preparations, bismuth offers a valuable substitute.

3. Arsphenamine can be counted on to deliver the strongest initial attack against *Spirochaeta pallida* and acts to best advantage when reinforced by one of the heavy metals; but if for any reason an arsphenamine is contraindicated, bismuth will probably give the better performance alone.

4. For those who would minimize the chances of ill effects and for those who hold that the parasite may become drug fast, alternating the two metals offers an obvious advantage.

## VIABILITY OF BACTERIUM TULARENSE IN HUMAN TISSUES

LEE FOSHAY, M.D.

College of Medicine  
CINCINNATI

AND

O. B. MAYER, M.D.

COLUMBIA, S. C.

W. H. H., a white man, aged 49, a master mechanic, dressed a rabbit that had been killed by his son, Jan. 12, 1935. Previously his health had been excellent and his weight had averaged 175 pounds (79.4 Kg.). January 15 he had a severe chill for two hours, followed by high fever and marked loss of strength. The next day he could scarcely speak above a whisper. January 18 a sore appeared on the right third digit near the nail root. The entire arm became painful, and tender swellings developed at the elbow and in the axilla. The temperature was 104 F. and remained so for the next three days. After January 21 he was out of bed, sitting around his home, with moderate fever, little malaise, profound weakness, drenching sweats, and pain limited to the right hand and arm.

January 24 he walked to the office and gave the foregoing history. On examination he was well developed, slightly pallid and obviously ill. His weight was 161 pounds (73 Kg.) and his height 65½ inches (166 cm.). The right pupil was slightly larger than the left. There was a small anterior perforation of the nasal septum. The neck, thorax, heart and lungs were normal. The blood pressure was 100 systolic, 80 diastolic. There were no abnormalities of the abdomen, genitalia or rectum. All reflexes were normal, and the extremities were normal, except the right upper. The dorsal surface of the terminal phalanx of the right middle finger showed an ulcerated, pustular lesion with surrounding purplish engorgement and redness extending up the dorsum of the hand to the wrist. The entire hand was swollen. A very large tender epitrochlear node was felt above the elbow. The overlying skin was desquamating. There was moderate enlargement of the axillary nodes but no other adenopathy. The temperature was 100 F.

The Wassermann and the Kahn reaction of the blood were negative. Smears were negative for malaria. Red blood cells numbered 4.48 millions, with hemoglobin 88 per cent. The white blood cell count was 10,400: polymorphonuclears, 72 per cent; lymphocytes, 25 per cent; transitionals, 3 per cent. There was moderate achromia. The urine was clear, acid, with a trace of albumin, no sugar, a few finely granular and hyaline casts, and bile two plus.

Intradermal injection of deaminized *Bacterium tularense* suspension gave a moderate positive reaction the next day and a markedly positive one forty-eight hours later. Blood serum agglutination, performed at the National Institute of Health Laboratory, gave partial agglutinations in dilutions 1:10 and 1:20.

January 31, 30 cc. of antitularense horse serum was given by vein. The primary lesion, finger and hand were improved by February 6, but the general condition remained unchanged. Mild serum sickness, with arthralgias of the right ankle and left shoulder occurred, February 9, and lasted for three days. In view of the continued weakness, drenching sweats and loss of weight (to 149 pounds [67.6 Kg.] February 11) it seemed that he should have been given more serum. As it was considered unwise to repeat horse serum in the presence of serum sickness, 20 cc. of antitularense goat serum was given by vein, February 11. An intradermal test made with this serum again gave the characteristic bacterial specific response. Following the second injection of serum the fever subsided promptly and the residual symptoms disappeared. The primary lesions were healed by February 20, and the nodes were less than half their former size. The patient resumed his usual work, March 15, having been disabled for two months. February 16, a serum agglutination test at Washington gave complete agglutination through 1:2,560 dilution. March 23 the epitrochlear node was still enlarged, tender and somewhat painful. The weight was 153 pounds (69.4 Kg.). He had been generally afebrile except for an occasional rise to 99.4 F.

April 18 the right elbow became swollen again, red and tender. This lasted for one week, then subsided spontaneously. May 11 the swelling occurred again. The temperature was

98 F., and the weight was 157 pounds (71.2 Kg.). By May 18 the swelling was sharply localized in the region of the olecranon bursa, accompanied by increased local heat, redness and definite fluctuation. About 6 cc. of bloody, turbid, ropy fluid was aspirated from the bursa and a compression bandage applied. Smears of the fluid showed many red blood cells and lymphocytes, no polymorphonuclears and no bacteria. The fluid agglutinated *B. tularense* completely through 1:1,024 dilution. A guinea-pig was injected subcutaneously with 2 cc. of fluid, May 21. Each of two blood-cystine-dextrose agar slants was inoculated with several loopfuls of fluid. After three days one slant showed 7 colonies that were typical for *B. tularense*. Stained smears showed minute gram-negative coccoid and bacillary forms. Dermal inoculation of a guinea-pig with one colony caused death on the fourth day. The autopsy gave results typical for rodent tularemia, and cultures from the heart blood yielded a pure growth of *B. tularense*. The guinea-pig that had been injected with the bursa fluid died after three and one-half days. The autopsy was typical and the heart blood cultures yielded a heavy growth of *B. tularense*.

Apart from the mild annoyance of a tender elbow the patient felt well. He remained afebrile and continued to work. He reported again, June 15, and stated that he was as well as he had been prior to the onset of the infection in January. The bursa was still swollen and fluctuant, and overlying tissues were mildly inflamed. Aspiration yielded about 5 cc. of ropy, turbid amber fluid. He was bled again for agglutinins. Serum agglutination was complete for *B. tularense* through dilution 1:640 and almost complete in 1:1,280. There was no agglutination against *Brucella* or *Proteus* OX<sub>10</sub>. The bursa fluid agglutinated *B. tularense* completely to 1:512 and partially to 1:1,024. Smears of the fluid (Gram stain and Nile blue sulfate stain, as before) showed: lymphocytes, 95 per cent; mononuclear cells, 2 per cent, and polymorphonuclears, 3 per cent. There were few erythrocytes. Along the thicker ropy parts of both smears were scattered bacteria, singly or in groups of from three to five, all minute rods, morphologically and tinctorially indistinguishable from *B. tularense*. There was no cellular karyorrhexis and no bacteria were seen intracellularly. Two slants of blood-cystine agar were inoculated with the fluid. After forty-eight hours' incubation one slant showed 4 colonies and the other 3 colonies, all typical of *B. tularense*. Dermal inoculation of a guinea-pig caused typical tularemic death on the fourth day, and pure cultures of *B. tularense* were recovered from the heart blood at autopsy. Another guinea-pig had been injected subcutaneously with 1 cc. of the bursa fluid. This animal died three and one-half days after injection. Autopsy showed typical rodent tularemia, and pure cultures of *B. tularense* were recovered from the heart blood.

The patient was seen again, July 15. He had continued to be well. The epitrochlear node never suppurated and was now quite small. The olecranon bursa was still enlarged but no fluctuation was demonstrable. Attempted aspiration gave only a few drops of bloody fluid, possibly not from the bursal cavity. Cultures of this fluid remained sterile and guinea-pig inoculation caused the animal no harm.

While at rest, September 17, the patient was seized suddenly with severe pain in the epigastrium, referred to the precordium and down the left arm. Pain was cramplike, accompanied by nausea and vomiting. It soon disappeared, to recur suddenly and more severely two nights later, at which time it lasted for one and one-half hours. There had been no previous attacks. The temperature varied from 99 to 101 F. for forty-eight hours, and the pulse rate was from 40 to 50 per minute. The white blood cells numbered 6,200, with polymorphonuclears 71 per cent, lymphocytes 29 per cent. The Wassermann reaction was negative. An electrocardiographic tracing showed complete heart block and evidences of coronary disease. The blood pressure was 120 systolic, 80 diastolic. A second electrocardiogram five days later showed normal conduction and a ventricular rate of 90 per minute. For this last information we are indebted to Dr. J. H. Gibbs, who saw the patient during the heart attack and who will report more extensively on the cardiac involvement elsewhere.

#### COMMENT

We know of four patients who have died abruptly following sudden severe substernal or precordial pain during convalescence from tularemia. Only one had

had symptoms of angina prior to tularemic infection. One case, that of a man, aged 36, who died suddenly, came to necropsy and will be reported in detail by K. V. Kitzmiller. The additional burden of tularemic infection, with possible coronary arteriolar endothelial proliferation, is more than hearts previously impaired by atheroma, sclerosis or syphilitic vascular disease can stand. Persons in the atheroma or sclerotic ages should be watched with special care during convalescence from tularemia. Elevated ventricular rates, palpitation and substernal discomfort indicate a need for careful cardiac examination. By doing so the physician and the patient may be forewarned, and appropriate rest or therapeutic measures may be taken to prevent possible impending death. In our patient the anginal symptoms and heart block occurred just eight months after the onset of tularemia.

The unusual feature, to us, was the prolonged presence in pure culture of highly virulent *B. tularense* within the bursal cavity, associated with signs of regional low grade subacute or chronic inflammation, but without accompanying fever or other symptoms or signs of illness or intoxication. We know of no previous instances of tularemic bursitis and cannot say whether such lesions usually suppurate. In this instance impending suppuration was not apparent. The cellular response was predominately lymphocytic, and phagocytic cells appeared late and were extremely few in number. It is possible that specific serum therapy may have aided in maintaining the quiescent status of the bursitis and in preventing the occurrence of systemic symptoms. The increasing natural immunity acquired by recovery may have served similarly.

It is not rare for tularemic infection to lie apparently dormant in certain patients for long periods after what appears to be complete clinical recovery. Residual infection is usually betrayed by sudden reenlargement of some previously involved lymph node. Very rarely late enlargement and suppuration have occurred in nodes not known to have been involved previously. Recurrent adenopathies have appeared as late as one year or more after cessation of all disability but are most frequent during the first four months. In more than half of these cases the nodes suppurate, sometimes with a very slight degree of regional inflammation and often with little or no constitutional reaction. Many of them behave like cold abscesses, and after incision or spontaneous rupture healing is often amazingly rapid and residual abscess is rare. Judged by cultures and animal inoculations the pus is usually sterile. Nodes that suppurate early in the illness are prone to contain viable bacteria.

Viable virulent bacteria have been recovered from other patients late in the disease. Five months after the onset of infection Ryan<sup>1</sup> recovered a pure culture through guinea-pig inoculation with pus from a draining axillary abscess incision. The patient had been afebrile for about three months before the recurrent bubo became apparent. The guinea-pig died on the tenth day after subcutaneous injection. A second animal passage (infected splenic pulp to shaved abdominal wall) caused death in six and one-half days. These survival periods suggest some attenuation of virulence of the strain. Kilbury and Fulmer<sup>2</sup> record recovery of a virulent strain by animal inoculation with ascitic fluid obtained three months after the onset of ulceroglandular tularemia. The acute phase and initial disability

2. Kilbury, M. J., and Fulmer, S. C.: Tularemic Peritonitis; Report of Case Observed for Four Years, *South. M. J.* 24: 856 (Oct.) 1931.

had lasted for about three weeks. It was only after resumption of work that the patient noticed progressive gradual enlargement of the abdomen. The constitutional symptoms were astonishingly mild despite the tularemic general peritonitis. Disability recurred, however, and it was two and one-half years before normal work could be resumed. Blackford<sup>3</sup> recovered a virulent strain from a proliferative dermal lesion of the arm. Dermal biopsy was made three months after the onset of the disease. Pure cultures of *B. tularense* were secured by animal inoculation with a macerated piece of the tissue. The remainder of the tissue, sectioned and stained, showed organisms that were morphologically and tinctorially consistent with *B. tularense*.

Clinical evidence from other patients also points to prolonged survival of *B. tularense* in human tissues. Goodpasture<sup>4</sup> saw a recrudescence of severe symptoms several months after the onset of disease in one patient, and a recrudescence with fever for one week occurred in another patient one year after apparent recovery from the acute phase. Francis<sup>5</sup> records the occurrence of febrile relapses, one of six and one of eight days, in two cases of laboratory infection at ten months and at eight months after the onset of disease. Rickman<sup>6</sup> observed a patient who had had many recurrent bouts of fever, with nodal enlargements of the forearm, arm and axilla, over a period of two years. The most recent recurrence, beginning at about the twenty-first month of illness, was ushered in by constitutional symptoms almost as severe as the initial acute phase, with recurrent tender nodes of large size (3 by 5 cm., 2 by 3 cm. and the like). No nodes ever suppurred. Antitularense serum (30 cc. intravenously) effected a sharp reduction in the size of all nodes and caused a marked amelioration of symptoms, but it is not known whether this improvement was permanent. We have also studied a patient with chronic tularemia, a woman whose initial infection occurred in December 1927 and whose diagnosis was confirmed by repeated agglutination tests at the National Institute of Health Laboratory. The acute phase, with temperature to 104 F., lasted for six weeks. An axillary node suppurred in February 1928. Later that year four abscesses occurred, one on a leg and three on fingers. For five and one-half years after the onset she was forced to go to bed for approximately two months out of each year because of fever, malaise, sweats, recurrent adenopathies, profound weakness and mental depression. Antitularense serum (20 cc. by vein) was given sixty-five months after the onset, causing a prompt reduction of fever and transient amelioration of symptoms. No permanent improvement was secured. She is still ill with intermittent symptoms and recurrent adenopathies eight years after the onset of disease.

One of the prominent features of tularemia is the prolonged persistence of agglutinins in the serums of recovered patients. Also, the degree of immunity conferred by recovery is not surpassed by that of any other infection known to us. With the exception of one extremely mild second infection in a heavily exposed laboratory worker, reported by Francis,<sup>7</sup> and recognized as such only because of his exceptional zeal,

no second attacks of the disease are known. This seems especially significant, even at present when the total experience with the disease is not great, for the occupational exposure hazard among butchers, market men and game skimmers is fairly high. It is inconceivable to us that all the immune persons in this occupational group should have escaped contact with infectious materials or that every disease producing reinfection should have eluded detection during the past decade when accurate recognition of the disease has become widespread, when diagnostic aids of great reliability have been widely available and when disability due to the disease has been compensable in certain states under workmen's compensation acts.

We interpret the permanent persistence of serum agglutinins, the freedom from second attacks and the persistent positive responses to intradermal injections of *B. tularense* suspensions and to injections of antitularense serum to mean permanent residual living bacteria held in certain tissues in innocuous equilibrium as far as their capacity to produce disease is concerned. Goodpasture<sup>4</sup> has previously expressed this belief in regard to tularemia, and Mooser<sup>8</sup> has adduced strong evidence indicating comparable situations in other infectious diseases. Late relapses and recrudescences indicate a recurring dominance of bacterial activity over the inhibiting factors. Similar conditions seem to obtain only in those infections which usually confer permanent protection after recovery from one attack. The recurrent typhoid abscess of the sternum recently reported by Gannon<sup>9</sup> is interesting in this regard. The recurrent local lesion first attracted attention five years and eight months after apparent complete recovery. Aspiration of the abscess five weeks later gave pus which yielded pure cultures of typhoid bacilli.

Careful studies of animals inoculated with tissues removed at necropsy from recovered tularemia patients who have died from other causes would be extremely useful, and they might confirm the hypothesis of residual living antigen. We have hoped for such an opportunity but, so far, without success. We hope that others to whom it may come will be interested in pursuing it.

#### SUMMARY

A patient with the ulceroglandular form of tularemia, treated by antiserum, developed tularemic infection of the olecranon bursa three months after onset of the disease and one month after cessation of disability. No constitutional symptoms accompanied the bursitis. Regional symptoms and signs, and the cellular reaction within the bursal fluid, indicated a mild subacute or chronic infectious process. Viable virulent *B. tularense* was obtained from the fluid by direct cultures and by animal inoculations four months and five months after the onset of illness, corresponding to the second and third months after cessation of all disability. *B. tularense* was seen in stained smears of one specimen of the fluid. *B. tularense* can survive in certain tissues of recovered patients for long periods. The ultimate outcome of these bacterial seclusions seems to depend on the solidity of the established bacteriostatic equilibrium.

Tularemic infection is a distinct danger to hearts with preexisting vascular disease.

## Clinical Notes, Suggestions and New Instruments

### ALLERGIC SYNOVITIS DUE TO INGESTION OF ENGLISH WALNUTS

PHILIP LEWIN, M.D., AND SAMUEL J. TAUB, M.D., CHICAGO

Bilateral chronic synovitis or intermittent hydrarthrosis appears in attacks of such striking periodicity that an allergic basis for these attacks is strongly suggested.

In 1924 Miller and Lewin<sup>1</sup> were the first to suggest that idiopathic hydrarthrosis is a sensitization disease, basing their evidence on the satisfactory response of this condition to injections of peptone intravenously.

Judging from the sparse literature since this observation, very little attention has been given to this group of cases, with the exception of Rowe,<sup>2</sup> who reported a case of intermittent hydrarthrosis that proved to be due to food sensitization. Skin tests were mostly negative in this case and the causative foods were determined by means of his elimination diets.

We report a case of intermittent hydrarthrosis of the knee due to ingestion of English walnuts. By allergic synovitis we mean a swelling, hyperemia and overactivity of the synovial membrane manifested by swelling, limitation of motion, increase of free fluid and a feeling of constriction in the joint.

#### REPORT OF CASE

H. W., a high school boy, aged 16, consulted one of us (P. L.) Jan. 25, 1930, because of stiffness and swelling, which had occurred intermittently for ten years. There had been periods during which the attacks occurred every two or three months. Swelling came on suddenly and disappeared, usually within twenty-four hours. Several joints were loose but none other than the knees became swollen.

The patient did not sneeze and had never had asthma, urticaria or eczema. His father had hay fever and his paternal uncle had hay fever and asthma. His mother had had urticaria from eating tomatoes or strawberries. He was referred to one of us (S. J. T.) for investigation of allergic factors.

It was found that the ingestion of the meats of half a pound of English walnuts was followed within seventy-two hours by a typical attack. Sensitization tests were made, both cutaneous and intradermal, with a positive reaction to English walnuts only. He was advised to avoid all nuts in the diet and to return in four weeks. Within two weeks the swelling and stiffness in the knees had cleared up completely. When the patient reported after an interval of four weeks, both knees appeared normal.

One-tenth cubic centimeter of the patient's blood serum was injected intradermally on the outer aspect of the left arm and 0.1 cc. of 5 per cent dextrose solution was injected in the right arm as a control. The patient was told to eat a liberal amount of English walnuts and to look at both arms at hourly intervals for any sign of swelling, redness or itching over the areas where the injections were made. Within two hours a large wheal with redness and severe itching appeared over the left arm where the patient's blood serum had been injected, while the control arm remained normal.

Three days later he noticed swelling and stiffness in both knees similar to the previous attacks. This condition persisted for five or six days and then gradually subsided. The patient was seen again July 22 and reported that he had abstained from eating nuts and had had no recurrence of synovitis.

#### COMMENT

The possibility of food allergy should be considered in every case of idiopathic synovitis. A personal or family history of the common allergic diseases, namely asthma, hay fever, urticaria, angioneurotic edema, eczema or migraine, increases the likelihood that some form of sensitization is present.

Food sensitization should be ruled out by subcutaneous and intradermal skin tests, with all the foods entering into the routine diet of the patient. If these food tests are negative, elimination diets should be tried. One of us<sup>3</sup> reported the same type of reaction occurring with peanuts in a child who

had eczema and asthma, only in this case the experiment was reversed. A small amount of the child's blood serum was injected into the arm of a nonallergic individual, and when peanuts were eaten he noticed a large hivelike swelling over the injected area one and a half hours later. This type of test was first described by Walzer in fish-sensitive patients. This type of synovitis is frequently due to sensitization of the joint tissues, and foods are probably the main cause.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.  
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The articles will be continued from time to time in these columns. When completed, the series will be published in book form.—ED.

### THE THERAPY OF ITCHING (PRURITUS)

IN COLLABORATION WITH DR. THEODORE CORNBLEET

The first principle in the treatment of itching is that scratching must be prevented, for scratching starts and maintains a vicious circle. It damages the skin, and the healing of the damage accompanied by itching again incites scratching. The scratching also insemminates and disseminates infection, which in turn makes the itching worse. Merely telling a patient not to scratch does no good when itching is infuriating, although the explanation as to why he must not may help in making him more cooperative. The patient should have some remedy that will relieve the itching at least as well as the scratching does. So detrimental to healing is scratching that, when the patient, e. g., a babe, is absolutely noncooperative, scratching must be made physically impossible by some form of restraint. For instance, in cases of facial infantile eczema a cardboard tube applied round the elbows in such a way that they cannot be flexed will serve the purpose.

There are two fundamentally different modes of attack in this as well as in any other nerve reaction: first, the lessening of irritation and, second, the lessening of irritability. These two are in inverse proportion of importance. The more completely the irritation can be removed, the less attention needs to be paid to irritability, and vice versa. As they are also complementary to each other, they are often well combined in the therapeutic program: for irritation increases irritability and increased irritability augments the effects of irritation.

#### LOCAL PRURITUS

From a practical point of view it is not so much the mode of therapeutic attack as the point of attack that might be employed in the classification of available means of treatment: (1) local measures, (2) systemic measures. These are again in inverse proportion of importance. Obviously, when local measures suffice, general measures are not required; and, the less efficient the local treatment, the more are systemic measures required. In general pruritus, systemic treatment is likely to be of greater importance than local therapy and in localized pruritus local treatment is of the greater importance. Often, these two points of attack are usefully combined.

1. Miller, J. L., and Lewin, Philip: Intermittent Hydrops of the Knee, J. A. M. A. 82:1177 (April 12) 1924.  
2. Rowe, J. A.: Food Allergy, Philadelphia, Lea & Febiger, 1931, p. 374.  
3. Taub, S. J.: Allergy Due to Silk, J. Allergy 1: 539 (Sept.) 1930.

**Local Measures.**—The ideal remedy for the relief of itching is the removal of the cause. When there is a definite skin disease, the causal therapy indicated is employed; e. g., that of skin infestation (q. v.), of eczema (q. v.) or of urticaria (q. v.).

In anal pruritus, one must look most especially for local rectal pathologic conditions, such as hemorrhoids, fistula or fissure and for ringworm, yeast or bacterial skin infection, and for infestation with pinworms, especially in children.

A vaginal discharge may produce anal pruritus.

Vulvar pruritus may be due to local genito-urinary disease, pregnancy, sexual maladjustment, or the menopause. Any one of the causes of rectal pruritus may give rise to vulvar pruritus. It must be understood, however, that all forms of local pruritus, anal as well as vulvar, may be due to any one of the causes of general pruritus (q. v.).

**PRESCRIPTION 1.—Boric Acid Dusting Powder**

R	Boric acid .....	6.00 Gm.
	Zinc stearate .....	30.00 Gm.
	Talcum .....	30.00 Gm.

Apply freely.

Because of the importance of local discharges or infection in maintaining anal and vulvar pruritus, strict cleanliness is the most important measure of hygiene. Thus, it is well to wash the anus after each defecation with 1 per cent dilution of Saponated Cresol Solution and to follow this with thorough drying and a dusting powder (e. g., prescription 1). In vulvar pruritus the liberal powder application should be kept in place by a clean vulvar pad, especially if there is any amount of discharge.

As the removal of the cause may require time and because, even after the cause is removed, its effects tend to persist and as furthermore immediate relief of itching is demanded, remedying the existing pathologic condition is of great practical importance. Itching, like pain—unless purely psychic—is always due to “nutrition minus” of certain nerves; itching is due to “nutrition minus” of the free intra-epithelial nerve endings. This “minus” may be qualitative, as in the poisoning of nerve endings in jaundice or in morphinism and in systemic pruritus in general, or quantitative, as is more commonly the case in localized pruritus as the result of increased tension within the derma, whether this is due to the presence of exudate or of any other disproportion between fluid pressure and epidermal surface rigidity or to the existence of cellular infiltration or of connective tissue overgrowth. If this theory is correct, itching cannot occur without a relatively rigid epidermis and a relatively active blood circulation. Scratching relieves the itching by damaging the epidermis, thus lessening tension. Anything that increases the blood supply increases itching, as does woolen underwear or the removal of clothing at bedtime and the congestion of the skin produced by the warmth of the bed. Accepting this theory as a working hypothesis, one may relieve itching by (1) lessening the blood supply to the skin, (2) soothing the sensory nerve endings, (3) softening the epidermis and (4) depressing the sensory nerves. By a suitable choice or combination of these, any form of pruritus may be relieved, at least temporarily. Most obstinate and difficult to relieve is the itching due to cellular infiltration or to fibrous tissue overgrowth in the derma. Such itching resists other forms of treatment save (5) destruction of the cellular infiltrate or of the affected nerves or tissue. As fibrous tissue overgrowth may become the

final state in any case of long standing pruritus, no matter what its origin, the obvious lesson is that itching must not be permitted to become chronic.

1. **Lessening the Blood Supply to the Skin.**—Because the cooling effect of the evaporation of fluid causes vasoconstriction, evaporating applications to the skin are favorite remedies in pruritus; curiously enough, the application need not be cold. Indeed, cold applications that are followed by reactive hyperemia may aggravate rather than relieve itching.

(a) **Alkaline lotion.** Water, applied as hot as can be borne, by bathing, on a compress, or by sponging and then not drying the skin, is a good antipruritic measure because the heat itself is analgesic and because of the succeeding reactionary vasoconstriction which is prolonged by the cooling effect of the evaporation of fluid. Adding alkali, e. g., about 5 per cent of Sodium Bicarbonate, to hot water increases the antipruritic value of this measure, probably by reason of the epidermis softening effect of alkali. To follow this sponging by dusting the still moist surface liberally with Talcum helps by retaining the moisture on the skin, and possibly also by protecting the sensory nerve endings. Adding 0.5 per cent of menthol to the dusting powder (prescription 2) adds a specific nerve-end depressing effect to the entire procedure. Thus, these measures combine the first four mentioned modes of relieving pruritus in one simple attack. This combination is indicated only in those conditions of itching in which the epidermis itself is not damaged, and when there is no tendency to vesiculation.

**PRESCRIPTION 2.—Mentholated Talcum**

R	Menthol .....	0.50 Gm.
	Alcohol .....	5.00 cc.
	Talcum .....	100.00 Gm.

Use freely as dusting powder.

**PRESCRIPTION 3.—Menthol-Boric Acid Solution**

R	Menthol .....	0.015 Gm.
	Boric acid .....	10.000 Gm.
	Water .....	500.000 cc.

Apply on gauze compress.

(b) **Isotonic lotions.** In conditions in which softening and epidermis-macerating applications are not suitable, as in acute eczema, the addition of from 2 to 4 per cent of Boric Acid (prescription 3) to the water, to make the solution used for the sponging isotonic or hypertonic, overcomes the objection arising from hypotonicity.

(c) **Astringent evaporating lotions.** These are still more suitable for those exudative dermatoses, e. g., “weeping” eczema, in which hot alkaline lotions are contraindicated. When the most acute stage of excessive irritability—which indicates soothing—has passed, compresses of Solution of Aluminum Subacetate diluted 1 to 10 are useful.

2. **Soothing the Nerve Endings.**—For the purpose of soothing the sensory nerve endings of the skin one may use:

- (a) Calamine lotion, if a drying effect is desired, or  
(b) calamine liniment, if emollient action is aimed at.

**PRESCRIPTION 4.—Phenolated Calamine Lotion**

R	Phenol, liquefied .....	0.60 cc.
	Calamine lotion .....	120.00 cc.

Apply freely.

In either case the addition of 0.5 per cent of phenol—the less the better—may increase the antipruritic value of the lotion (prescription 4).

(c) **Films.** These are still more efficient in that they not only protect the skin against the irritation of air and the contact with clothing but also because they

lessen the influx of blood by their pressure and, maybe most especially, because they prevent scratching. The Soft Zinc Glycrogelatin of the National Formulary is not only useful for application as Unna's boot in the treatment of varicose eczema (cf. Therapy of Varicose Veins) but might also be a valuable recourse in other conditions of pruritus. The Paraffin Dressing (cf. Therapy of Burns) may as well be employed in pruritus as in burns. A "drying paste" is useful as a protective varnish on the face in infantile eczema. It may be made more antipruritic, if necessary, by the addition of a small amount of phenol (prescription 5).

#### PRESCRIPTION 5.—Phenolated Drying Paste

℞ Phenol, liquefied .....	0.50 cc.
Tragacanth .....	5.00 Gm.
Glycerin .....	2.00 cc.
Water.....to make	100.00 cc.

Apply to itching part and permit to dry.

When there are excoriations due to scratching, unguent paste treatment should be employed because of its epithelizing effect. One may use Paste of Zinc Oxide for rather localized patches, or the Soft Paste of Zinc Oxide for more extensive application. In either case final liberal dusting with talcum forms a crust that tends to keep the paste in place.

3. *Softening the Epidermis.*—Softening of the epidermis is especially indicated when the skin is harsh and dry, as in senile pruritus. In this condition, brushing the skin with a soft hair brush while the patient is in a warm alkaline bath (sodium bicarbonate one-fourth pound to the tub) may remove an abundance of harsh dead epidermal scales that contribute to maintenance of the itching. Following this with an inunction of Rose Water Ointment leaves the skin in a much more wholesome condition than it was before.

While ointments are useful when the skin is harsh and dry, they should generally be avoided in pruritus of the anus or vulva, as in these locations they are "messy," macerate the skin, and may aggravate the trouble. It is only when extreme dryness prevails in these parts that the sparing use of salves may be permissible.

4. *Depression of the Sensory Nerves.*—(a) By volatile analgesic. This is accomplished by such agents as menthol, phenol and other coal tar derivatives in varying application forms, dependent on the extent of the affliction and the condition of the affected skin. They should be given the patient to be applied in lieu of scratching. The permissible concentration of the analgesic agent depends on the irritability of the surface. When the skin is acutely irritated, they must be employed in great dilution, as they have irritative qualities which may result in aggravation of the irritation and the itching after the nerve depression has worn off. When the skin is not very irritable, they may be employed in considerable concentration, as in the following applications, listed somewhat in order of ascending strength:

#### PRESCRIPTION 6.—Menthol-Phenol Ointment

℞ Menthol .....	0.30 Gm.
Phenol .....	0.60 Gm.
Rose water ointment.....	30.00 Gm.

Apply locally as required, and instead of scratching.

#### PRESCRIPTION 7.—Menthol-Phenol Lotion

℞ Menthol .....	0.30 Gm.
Phenol .....	0.60 Gm.
Alcohol .....	30.00 cc.

Apply locally.

Menthol and Phenol: Ointment (prescription 6) may be ordered in double strength of the active ingredients unless the skin is quite sensitive. Because it is more

cleanly and more easily applied, an alcoholic solution of these (prescription 7) is preferable, if the skin is not in need of an emollient. Menthol had better be omitted in senile pruritus because it may give rise to the complaint of chilliness.

#### PRESCRIPTION 8.—Mentholated Coal Tar Lotion

℞ Menthol .....	0.30 Gm.
Glycerin .....	8.00 cc.
Solution of coal tar.....	60.00 cc.
Solution of calcium hydroxide.....to make	120.00 cc.

Apply to itching surface.

Coal Tar Solution: Usually ordered to be diluted with nine parts of water, Coal Tar Solution may be employed even in full strength or in the form of the mixture given in prescription 8 if the skin is not damaged.

Pigment: Camphorated Phenol may be employed even in full strength, e. g., in the treatment of anal pruritus, without danger of damage to skin or mucous membrane. It is usually strong enough when mixed with an equal part of Zinc Oxide Ointment (prescription 9).

#### PRESCRIPTION 9.—Camphor-Phenol Ointment

℞ Camphorated phenol .....	15.00 Gm.
Zinc oxide ointment.....	15.00 Gm.

Apply locally as often as required.

(b) *Infiltration anesthesia.* Decided temporary relief may be obtained by infiltration of the affected skin with as much as 75 cc. of 0.5 per cent procaine solution, injecting enough to make the entire region edematous. In some cases a single injection suffices to break in on a vicious circle. In others, the treatment has to be repeated at intervals.

Should the itching return too soon after infiltration with a water-soluble anesthetic, one may take recourse to infiltration with an oil-soluble anesthetic of prolonged action, e. g., Nupercaine (N. N. R.) in the form of Gabriel's solution (1930), which has the formula given in prescription 10.

#### PRESCRIPTION 10.—Nupercaine Oil

℞ Nupercaine (base) .....	0.50 Gm.
Phenol .....	1.00 Gm.
Benzyl alcohol .....	10.00 cc.
Oil of sweet almond.....to make	100.00 cc.

Dispense in sterile 5 cc. ampules.

Simmons<sup>1</sup> recommends the following technic for pruritus ani: After cleansing the anal region, 5 cc. of this solution is injected under the itching area. One may inject the posterior quadrant on the first visits and the lateral and anterior quadrants on subsequent visits. The finger should be inserted into the anal canal to guide the direction of the needle and avoid penetration of the rectal mucous membrane, which might cause infection. Pooling of the oily solution should be avoided, as it may lead to painful induration. Intradermal injection may lead to a slough. Contraindications to these injections are local infection (eczema) and possibly idiosyncrasy to the drug (if such exists).

(c) *Division or resection of sensory nerve.* The division or resection of the sensory nerve supplying the affected part is the supreme remedy to be employed, when other measures fail to relieve constant and maddening pruritus due to irremediably damaged skin, although excision of the skin may first be tried provided previously employed roentgen therapy in safe dosage has failed. Removal of the affected skin and mucosa is especially indicated when the presence of leukoplakia renders malignant changes a possibility.

1. Simmons, N. J.: Pruritus Ani—A New Treatment, *Am. J. Digest. Dis. & Nutrition* 2: 53 (March) 1935; *Elimination of Postoperative Pain Following Hemorrhoidectomy*, *New England J. Med.* 214: 20 (Jan. 2) 1936.

**5. Destruction of Cellular Infiltrate by Radiation Therapy.**—This method of treatment of itching may also act in some other way, as it has also been useful in "essential pruritus." Relief may be obtained from a single exposure to 25 roentgens of unfiltered rays. The treatment may be repeated two or three times at intervals of three or four weeks. More must not be taken, to avoid the induction of erythema. Because of their more limited penetration, grenz rays should be preferable when it is necessary to avoid injury to important organs in or under the skin.

**Systemic Measures.**—It is important to remember that strictly localized pruritus may be due to systemic causes and cured by proper care of these; also that systemic treatment which acts by lessening irritability may advantageously be combined with the local measures discussed. It is only for purposes of classification that the discussion of these is undertaken under separate headings.

#### GENERALIZED PRURITUS

Generalized pruritus is said to exist when the condition affects large areas of the body surface. It rarely affects the whole body at one time. As "removing the cause" gives most radical results, this should, of course, always be first attempted.

**1. Causal Treatment.**—The body surface should receive first consideration. Thus, one should always think of scabies and body lice, even in the most genteel.

Excessive dryness of the skin is responsible not only for "senile pruritus" but also for "bath pruritus" and for "winter itch" (pruritus hiemalis). Whenever the skin is dry, the use of soap should be restricted to the hairy parts and the hands and feet. The patient should bathe in the daytime rather than before retiring. Luke-warm rather than hot water should be used for the baths. The skin should be permitted to remain slightly moist after the bath, and a soothing ointment applied immediately after it. Proper moistening of the air of living rooms (between 40 and 60 degrees of relative humidity) is of great importance. Sleeping rooms should be kept cool. Flannel blankets and woolen underwear next to the skin are particularly obnoxious. Cotton or silk undergarments should be worn with a woolen garment over this if desired. Removal to a warm climate during the cold season is, of course, the most radical remedy for the "winter itch."

There is also such a condition as "summer pruritus" due to excessive sweating, and it sometimes occurs as an after-effect of sunburn. Modification of sweating or of skin blood supply (q. v.) may be helpful.

The patient's examination must be all embracing for the practice of causal therapy in pruritus. A partial list of the conditions in which pruritus may be the "presenting symptom" includes diabetes mellitus, liver and kidney disease, disturbances of the gastro-intestinal tract, blood diseases and allergy.

Diabetes mellitus is so important a cause of itching that urinalysis should be one of the first items in the examination of any case of pruritus. It is generally localized at the genitalia, owing to the irritation set up by fermentation of the sugar in the urine, and it disappears promptly when the glycosuria is controlled. Pruritus may also occur in other diseases of metabolism, such as hyperthyroidism, gout or obesity.

Liver and kidney disease are probably next in order. When itching occurs, as it usually does in jaundice, the causal association between the two is obvious. It is possible for liver disturbance to produce itching even

without the presence of frank jaundice. In such cases the bilirubin index may be high. Itching may be a distressing symptom of uremia.

Disturbances of the gastro-intestinal tract, such as constipation and indigestion, may be causes.

Blood diseases, especially leukemia, but also chlorosis, may be accompanied by itching.

Allergy to various foods may give rise to or aggravate pruritus. The foods more commonly concerned are shellfish, highly seasoned dishes, cheese, strawberries, tomatoes, pork and sausage. There may be no demonstrable urticaria and, indeed, the itching may occur almost immediately following ingestion of the food. Itching may occur in serum sickness and be an accompaniment of other allergic states, such as hay fever and asthma.

Some drugs tend to give rise to pruritus, particularly opium, belladonna and cocaine; and an untoward reaction to arsenic may first be indicated by itching of the palms and soles. Abuse of coffee, tea, alcohol and tobacco may be responsible for pruritus.

Elimination of the causative factor, when it is not obvious, may be attempted by diet, by favoring bowel evacuations, by diuresis, and even by "washing of the blood."

(a) Diet: Abstinence from highly seasoned or fatty foods, strong cheeses, tea, coffee, alcohol or tobacco may be helpful. When allergy is suspected, test diets (see Therapy of Urticaria) are indicated. An exclusively milk diet relieves all other forms of dietary allergy, excepting of course that due to milk, which would be aggravated by it.

(b) Bowel evacuation: Saline or alkaline saline catharsis, if there is a tendency to colon stasis (q. v.), should not be omitted from the therapeutic program.

(c) Diuresis: Cool retention enemas of 1 or 2 liters of 2 per cent solution of Sodium Bicarbonate given morning and evening may improve conditions, especially in jaundice.

(d) "Washing of the blood": Removing from 150 to 250 cc. of blood by vein puncture and injecting from 200 to 300 cc. of Physiologic Solution of Sodium Chloride may not so much act by actual removal of poison as by an "alterative" influence.

**2. Modification of Sweat Secretion.**—As not only deficient but also excessive sweat secretion may produce itching, it is not surprising that Pilocarpine Nitrate (8 mg.) as well as Atropine Sulphate (1 mg.) have been advocated in the treatment of pruritus. Even when the condition of the skin does not obviously indicate the one or the other, a trial of a hypodermic injection of either one may be worth while in certain cases, with continuance of oral administration of the dose that gives maximum benefit with a minimal side effect. Addition of the helpful agent to other medication may have a potentizing effect.

**3. Modifications of the Blood Supply.**—(a) Epinephrine. The almost magic effect of the intramuscular injection of Solution of Epinephrine Hydrochloride (0.5 cc.) in the therapy of allergic urticaria justifies its trial in allergic pruritus as well as in other forms in which a diminution of the skin blood supply seems indicated.

(b) Ergotamine tartrate. In a dosage of 1 mg. orally three times daily for several days, ergotamine tartrate has been especially recommended for pruritus of hepatic or renal origin. Several doses are required before the effect is noted; but then the pruritus may

not recur after discontinuance of the drug. Its use must not be continued indefinitely, owing to the danger of ergotism.

(c) Nitrites. These have been found useful in certain cases of general (not localized) pruritus. That vasodilation may be useful in pruritus need not be surprising when one thinks of pruritus as due to "nutrition minus" of skin nerves engendered by excessive intradermal pressure. The lowering of systemic blood pressure may lessen the intradermal tension at the same time as the blood supply to the skin is increased. The relief obtainable from vasoconstrictors, on the other hand, may be assumed to be due to the lessening of intradermal tension by diminution of the blood supply. Tablet of Glyceryl Trinitrate, now official in an average dose of 0.6 mg., dissolved under the tongue, has given relief within five minutes and for from one to two hours. Diluted Erythrityl Tetranitrate (erythrol tetranitrate) in doses of 0.03 Gm. may give within half an hour relief that may last for five or six hours. As the relief of the itching occurs simultaneously with the blushing of the skin and the congestion in the head, one may know that, when relief is not experienced at the onset of these symptoms, the nitrites are not of any use in the particular case. Habituation, which develops after several days and interferes with continuance of the antipruritic action, requires discontinuance of the drug for possibly two days to secure the return of effectiveness.

4. *Influencing of the Central Nervous System.*—The fact that pruritus is akin to pain is well brought out by the fact that analgesics are also, in general, antipruritics. Opiates are a notable exception to this proposition. They are particularly prone to induce or aggravate itching.

(a) Acetylsalicylic Acid in doses of 0.30 Gm. in capsule or tablet form may be given every two to four hours as required. If it is not well borne, on account of diaphoresis, one of the coal tar analgesics such as Aminopyrine (0.30 Gm. capsules or tablets) may serve as a succedaneum.

#### PRESCRIPTION 11.—Bromide

R Potassium bromide . . . . . 30.00 Gm.  
Anise water . . . . . 30.00 cc.  
Syrup of glycyrrhiza . . . . . to make 120.00 cc.  
A teaspoonful or two in milk after meals and at bedtime.

#### PRESCRIPTION 12.—Bromide and Cannabis

R Sodium bromide . . . . . 8.00 Gm.  
Fluidextract of cannabis . . . . . 1.00 cc.  
Iso chlor . . . . . to make 120.00 cc.  
Tablespoonful in water every four hours.

(b) Bromide in 1 to 2 Gm. doses (prescription 11) may lessen nervous irritability. The combination of bromide with cannabis (prescription 12) is synergistic

#### PRESCRIPTION 13.—Phenobarbital and Acetylsalicylic Acid

R Phenobarbital . . . . . 0.50 Gm.  
Acetylsalicylic acid . . . . . 5.00 Gm.  
Divide into fifteen capsules.  
One as required at bed time.

in pruritus in that the latter adds a psychic alternative action to the depressant effect of the bromide.

(c) Hypnotics, e. g., as phenobarbital (0.1 Gm. tablet), should be included in the therapeutic program when itching is worse at night or when it interferes with sleep. As a general rule, when a hypnotic is used alone in sleeplessness due to itching, it must be given in large doses: hence it had better be combined with an analgesic (prescription 13).

(d) The therapy of psychoneurosis (q. v.) is required in proportion to the dominance of neurosis;

but every patient with pruritis needs some psychotherapy. Knowing that "everybody itches more or less" may not be much consolation to one who is driven frantic by itching. It may, however, help some others to bear their affliction with more equanimity. Most especially must pruritus sufferers have driven into their minds the injunction "not to scratch," and to make this possible is the alpha and omega of pruritus therapy.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

### HOGAN SUPER-BREVATHERM SHORT WAVE DIATHERMY UNIT, MODEL 8898 ACCEPTABLE

Manufacturer: McIntosh Electrical Corporation, Chicago.

This unit is designed to produce undamped electric current oscillations of high frequency which are suitable for the production of heat within the body tissues, for surgical tissue cutting and for hyperpyrexia.

The apparatus is mounted in a wooden cabinet, all component parts being accessible for inspection and repairs. The circuit is of a well known two-tube type, with the two oscillator tubes connected in opposite phase relation. The plate circuits are supplied with direct current, which is obtained from a two-tube mercury vapor rectifier. Two oscillator and two rectifying tubes are employed in this unit.

The patient's circuit is inductively coupled to the plate or output inductance of the oscillator tubes. A variable condenser of the split stator type is used to tune the patient's circuit into electrical resonance with the oscillator. Sufficiently loose coupling between the plate inductance and the inductance of the patient's circuit prevents overload conditions of the tubes. For the regulation of the power output, the primary winding of the plate current transformer is equipped with taps to vary the input current. Under maximum load the power input is about 1,500 watts. Since there is no acceptable method for measuring the output of short wave machines, this value is not stated. A thermocouple amperemeter indicates the relative power output, and maximum readings indicate electrical resonance between oscillator and patient's circuit. The wavelength is approximately 21 meters.

The temperature rises of the transformers, after the machine was operated at full load for two hours, came within the limits of safety prescribed by the Council. Both cuff and pad electrodes are furnished as standard equipment. The shipping weight of the unit is about 200 pounds.

At the request of the Council the machine was investigated and the data submitted for consideration. The tissue heating effect in the human thigh was observed. Cuff electrodes were applied to the thigh: one posterior to the hip, the other anterior to the knee. Thermocouples were introduced into the deep-lying tissues and also into the subcutaneous tissues. They were placed at a point midway between the hip and the knee, or midway between the cuff electrodes, and removed during the time of treatment. After twenty minutes' treatment, the machine being operated at the patient's tolerance, the temperature rise and final temperature (average of five tests) were observed to be somewhat higher than those temperatures obtained by conventional diathermy, which was used as a control. The conventional diathermy currents were applied to the thigh by tinplate electrodes, one on the medial and one on the lateral aspect.

The cuff electrodes used in the investigation were made of metal surrounded by thick protecting felt and enclosed in a

Hogan Super-Brevatherm Short Wave Diathermy.

sateen bag. Several layers of toweling, a felt pad, or both materials, were placed next to the skin to absorb perspiration.

Burns may be produced by this machine, but they may be avoided by ordinary precaution; their likelihood to occur is much less than with conventional diathermy.

This unit was tested in a clinic acceptable to the Council, and there the reports of the investigation were confirmed, and

Schematic diagram of circuit.

the machine was considered as giving satisfactory service for the purpose for which it is intended.

In view of the favorable report of the machine, based on its performance when cuff electrodes were used, the Council on Physical Therapy voted to include the Hogan Super-Brevatherm Short Wave Diathermy Unit, Model 8898, in its list of accepted apparatus.

### SPENCER SUPPORTS ACCEPTABLE

Manufacturer: The Spencer Corset Company, Inc., New Haven, Conn.

Spencer belts, corsets with built-in supports, and bandeaux are recommended by the manufacturer for the following indications: enteroptosis, hernia, sacro-iliac sprain, movable kidney, pregnancy and post partum, postoperative support, and breast conditions. These supports are made for men, women, children and infants.

All Spencer supports, declares the firm, are constructed of nonelastic material and are made to order according to the information submitted by corsétières, the saleswomen for the company. This information consists of a description and measurement of the figure. The boning in Spencer supports is of special steel covered with a material claimed to be impervious to moisture. This boning is called Spencerbone, because it is manufactured exclusively for the firm and from its own formula.

**Spencer Abdominal Corset.**—A corset combined with a supporting section of fabric of proper stiffness, of a size and shape appropriate to the needs of the patient, which is worn inside the corset and adjusted from the outside by means of straps which emerge through slots. Each strap adjusts independently and permits varying degrees of pressure from the bottom to the top of this inner supporting section. Pressure and uplift, according to the firm, can be secured in any amount which the patient can tolerate. Especially designed padding can be used under any part of the section to give local pressure to whatever degree desired. The straps engage with flat buckles so located on the outside of the corset as to bring the strain of the abdominal uplift on the pelvic girdle.

**Spencer Abdominal Belt.**—A garment designed to do the same work as the Spencer Abdominal Supporting Corset; but,

unlike the corset, this abdominal belt is made of a corset back section coupled only to a somewhat larger abdominal supporting section by means of straps and buckles which operate the same as for the corset.

**Spencer Sacro-Iliac Corset.**—A combination corset with an inner belt, which encircles the pelvic girdle and emerges at the front. According to the company, it can be adjusted to varying degrees of pressure by means of straps and buckles. This inner band is adjustable independently of the corset and can be tightened to any desired degree. The corset's particular function is to keep the band from sliding up and out of place on the figure.

While this band is commonly fitted with a pad of proper shape which, when adjusted, rests over the sacrum, different sizes and shapes are made as ordered by the physician.

**Spencer Sacro-Iliac Belt.**—This belt is similar to the Spencer Abdominal Belt, except for the narrow pad and band fitted and adjusted to it. The purpose of it is to hold the sacro-iliac band in place on the figure.

**Buckle Front Corset for Back Support.**—This garment, states the manufacturer, is used when a fair degree of immobility of that part of the spine which it can control is desired. It is fitted with rigid or semirigid steels for each side of the spine. The garment is fitted with strong adjustable shoulder straps which, coming up from the back, pass over the shoulder and under the arm, fastening far enough back to limit the motion of the shoulders. Steels of lighter weight are used at the sides and front.

**Spencer Belt for Inguinal Hernia.**—A belt, according to the firm, which will control small, easily reducible, inguinal hernias. The belt itself provides support and uplift. Perineal straps are adjusted to cloth tabs attached to the bottom edge of the front part of the belt. Attached to these cloth tabs are firm, softly finished pads, placed to give the necessary pressure on the opening.

**Spencer Maternity Corset.**—An especially designed corset with lacers at front, back, and sides to provide for changes in the figure during pregnancy. It is designed either with or without the inner abdominal support.

**Spencer Maternity Belt.**—A Spencer abdominal belt, with an additional back lacer adjustment which provides for figure changes.

**Style 400 Bandeau.**—A bandeau designed to give bust support and uplift. Bust pockets are made of slightly stretchy material, shaped to provide uplift without constriction. Material below bust does not stretch. Made to the patient's bust and waist measurements.

**Style 700 Bandeau.**—A bandeau made of soft material, firm enough to provide bust support and uplift. Made to patient's bust and waist measurements.

**Style 800 Bandeau.**—A bandeau made of soft material, firm enough to give bust support and uplift. Suitable for those preferring a short bandeau.

**Pads.**—Pads which supply specific local pressure are made to sizes and thicknesses as specified by the physician.

According to the Spencer Corset Company, these supports are sold through their sales representatives (women), known as Spencer corsétières. The corsétières are not permitted to diagnose; they are required to cooperate with the physician by fitting the type of support he prescribes. They are also instructed to arrange for the physician's inspection of a completed and fitted garment, whenever it is possible. All garments are designed for the individual patient. The company claims that no stock garments are made or sold.

The Spencer Corset Company has informed the Council that it has never paid commissions or rebated any percentage of the selling price to physicians on any of its merchandise, and assures the Council that it will not do so in the future. Furthermore, the manufacturer has stated that the corsétières are under instructions not to pay commissions or gratuities of any kind and that any violation of this rule would cause them to lose their franchises.

These garments were examined by a consultant who has had a large experience with such supports. He reported that the supports gave satisfactory service.

The Council therefore voted to include the Spencer Supports in its list of accepted devices.

## Council on Pharmacy and Chemistry

### REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH, Secretary.

#### ANDROSTINE-CIBA NOT ACCEPTABLE FOR N. N. R.

Under the name "Androstine" the Ciba Company has been promoting three preparations, all claimed to be testicular extracts. Circulars recently distributed to the medical profession make many extravagant and unwarranted claims for this product; the Ciba Company has not submitted the product for the Council's consideration, and this report is made on the Council's own initiative.

According to the recent advertising, Androstine is represented to be

"a total testicular extract . . . composed of two fractions, the hydrosoluble, which contains the active principles of the spermatid gland, and the liposoluble, extracted from the interstitial gland."

It is claimed that

"The administration of Androstine to castrated animals provokes certain reactions, of which the most important is the increase in size of the capon's comb: this is the reaction employed for the standardization of Androstine."

Although the firm implies that Androstine is standardized by the capon comb-growth reaction, the marketed solutions are described as representing, in the combined contents of one ampule "A" (hydrosoluble) and one ampule "B" (liposoluble) (each 1.5 cc.), "the active hydrosoluble and liposoluble principles contained in 16 grams of fresh gland." There is no statement of potency in capon units. In addition to the ampules the firm markets tablets each claimed to represent "the active hydrosoluble and liposoluble principles contained in 8 grams of fresh gland."

The claimed indications for Androstine are:

"Testicular insufficiency, prostatic hypertrophy, impotence, infantilism, premature senility, obesity of endocrine origin, climacteric of man, prostatism, neuroses and psychoses of genital origin."

It is claimed further that:

"Androstine stimulates basal metabolism and relieves nervous and psychical troubles of sexual origin."

The prescribed dosage for these conditions is "3 to 8 tablets a day . . . or the contents of one ampule injected intramuscularly, using ampules A and B alternately."

A competent investigator communicated to the Council the results of assays made on both injectable forms of "Androstine." The investigator reported (in part) as follows:

"We gave each caponized rooster the amount recommended for one week's treatment of humans and obtained no increase in comb growth. Therefore I think we can say that both of their fractions, as supplied to us, contain less than one cock unit per 3 cc. of substance."

The following more detailed statement was submitted later:

"Of the ampules of Androstine which we had we made the following tests:

"The first set of capons were each injected with 1.5 cc. of ampules A and B on alternate days for six days. The reaction obtained was less than 1 cock unit. Another group were each given 4.5 cc. of ampule A in 3 divided doses. The same thing was done with ampule B. In both of the latter instances no reaction occurred. Therefore we had no evidence from our assay that there was any appreciable amount of male hormone in the doses prescribed."

It appears, therefore, that Androstine-Ciba is practically inactive with respect to its content of comb-growth-stimulating substance. As the latter principle is the only substance in testis extracts known at present from which any essential physiologic effect or possible therapeutic benefit might be obtained, the claims made for Androstine-Ciba are obviously unwarranted. Even if Androstine actually contained an appreciable amount of testis hormone, the clinical use of this principle is so poorly established that the claims made by the Ciba Company would still be unsupported by adequate evidence.

The Council declared Androstine-Ciba unacceptable for N. N. R. because it represents an irrational combination of inactive preparations, marketed with unwarranted and misleading claims.

## NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

#### DIGIFOLINE-CIBA (See New and Nonofficial Remedies 1935, p. 165).

The following dosage form has been accepted:

Ampules Digifoline Ciba. Each ampule contains 2 cubic centimeters of a 0.1% solution of digifoline in benzyl alcohol. Ciba equivalent to 0.1 Gm. (1½ grains) of digifoline. The solution is standardized by the Hatcher and Brody cat method so that each ampule represents one cat unit. It contains neither alcohol nor glycerin.

#### BISMUTH SODIUM TARTRATE-SEARLE (See New and Nonofficial Remedies, 1935, page 122).

The following dosage forms have been accepted:

Ampoules Bismuth Sodium Tartrate-Searle, 3 per cent, 2 cc.—Bismuth Sodium Tartrate-Searle, 0.060 Gm.; benzyl alcohol, 0.040 Gm., and sucrose, 0.50 Gm., in distilled water to make 2 cc.

Solution Bismuth Sodium Tartrate-Searle, 3 per cent, 60 cc. vial.—An aqueous solution containing in each 2 cc. bismuth sodium tartrate-Searle, 0.060 Gm.; benzyl alcohol, 0.040 Gm., and sucrose, 0.50 Gm.

## CORRECTION

Refined and Concentrated Antipneumococcic Serum Type VII-Lederle.—In the preliminary report of the Council (THE JOURNAL, May 2, p. 1564), first paragraph, last sentence of the paragraph, the statement ". . . type VIII includes a typical type III" should read ". . . type VIII includes atypical type III."

## Committee on Foods

### VITAMIN D MILK

#### THE RELATIVE VALUE OF DIFFERENT VARIETIES OF VITAMIN D MILK FOR INFANTS: A CRITICAL INTERPRETATIVE REVIEW

PHILIP C. JEANS, M.D.  
IOWA CITY

(Concluded from page 2069)

#### CLINICAL OBSERVATIONS

In the abstracts that follow, the quantities of vitamin D are stated in terms of U. S. P. or International units. In most instances conversion from other unitage statements has been necessary. It is to be recognized that conversion factors are to some extent arbitrary and that the results by the older methods of assay vary in different laboratories. The variations are presumably due to factors beyond the control of the most careful experimenters and may be so great as to lead to the conclusion that the older methods are inaccurate. No doubt some of the confusion that now exists concerning the relative values of vitamin D from different sources is dependent on the inaccuracies of assay of this vitamin by the older methods.

Daniels, Stearns and Hutton,<sup>22</sup> 1929: This was an inpatient balance study in which slightly better retentions of calcium and slightly poorer retentions of phosphorus were obtained with irradiated milk than with 5 cc. of cod liver oil. The authors conclude that cod liver oil in the amount used was less effective than irradiated milk. It is the reviewer's interpretation that the retention values represent a low vitamin D intake for both the cod liver oil and the irradiated milk groups. Calcium retentions of from 35 to 39 mg. per kilogram are about what may be expected from approximately

22. Daniels, Amy L.; Stearns, Genevieve, and Hutton, Mary K.: Calcium and Phosphorus Metabolism in Artificially Fed Infants, *Am. J. Dis. Child.* 37: 296 (Feb.) 1929.

135 units of vitamin D and the milk intake stated,<sup>16</sup> and considerably less than approximately 50 mg. per kilogram to be expected when from 340 to 350 units (one teaspoonful of cod liver oil) is given.<sup>23</sup> In the study under consideration the potency of none of the vitamin D preparations was determined. The milk was irradiated under a quartz lamp for a period sufficient to have a strong flavor develop, and the cod liver oil was an unrefined product purchased especially because of crudeness.<sup>24</sup> No conclusions can be drawn from this study for the purpose of this review.

Barnes, Brady and James,<sup>25</sup> 1930: In an outpatient study, rickets was cured or prevented in 95 per cent of sixty-four babies receiving 840 units of vitamin D daily as cod liver oil. At the end of the study, 98 per cent of the babies were either well or benefited. Rickets was cured or prevented in only 44 per cent of fifty-seven babies receiving 750 units of vitamin D as irradiated ergosterol. The results in the latter group "were not significantly better than those for the control group of untreated subjects." The cod liver oil and viosterol used were assayed for vitamin D content. Roentgenograms and serum calcium and phosphorus were the criteria. Lack of cooperation is stated for the mother of one of the two babies who developed rickets on the cod liver oil regimen.

De Sanctis and Craig,<sup>26</sup> 1930: This study is difficult to interpret because the potency of the cod liver oil was only estimated and rickets was diagnosed entirely by means of clinical signs. With viosterol at a daily level of 810 units of vitamin D, rickets developed in 23 per cent of the babies. With cod liver oil at an estimated vitamin D level of from 380 to 460 units of vitamin D daily, rickets developed in 3 per cent of the babies. Subsequent reports by the same authors give essentially the same type of results.

Hess, Lewis and Rivkin,<sup>27</sup> 1930: In this preventive study sixty infants from 4 to 12 months of age and housed in an institution were given 10 or 20 drops daily of viosterol in oil, beginning in the autumn and ending in March. It is estimated from data given by Bills<sup>28</sup> that 10 drops of viosterol in oil contained 2,860 units. The babies were outdoors almost daily. The proportion of infants receiving either dosage is not stated. The criteria were physical examinations from time to time and roentgenograms and calcium and phosphorus levels in the blood at the end of the study. The authors state that the type of disorder generally recognized as rickets was almost completely prevented but that as judged by the more refined methods the protection was not absolute. Of the entire group, ten developed mild rickets; two of these received 10 drops of viosterol in oil and eight received 20 drops. When the cases of clinical rickets are excluded and only those with roentgenographic rickets are considered, there remained three infants with slight rickets and one with slight to moderate rickets, all having received 20 drops

of viosterol in oil. The authors conclude that the dosage employed in this study (5,700 units) was inadequate.

The baby with slight to moderate rickets after the ingestion of 20 drops daily of viosterol in oil for two and one-half months was given six teaspoonfuls of cod liver oil daily. Slight healing was noted in ten days and complete healing in three weeks. The authors state that the 20 drops of viosterol in oil were equivalent to ten teaspoonfuls of cod liver oil on a rat unit basis. In this instance rapid healing was produced by approximately 2,100 units as cod liver oil in an infant whose rickets developed while he was receiving approximately 5,700 units as viosterol.

Hess, Poncher, Dale and Klein,<sup>29</sup> 1930: Viosterol in oil (286 units to the drop<sup>28</sup>) was administered in an outpatient preventive experiment to fifty-one infants in doses of 1, 2, 3, 5, 10, 15 and 20 drops daily. Cod liver oil was given to forty-one infants in doses of 1, 2 and 3 teaspoonfuls and 2 tablespoonfuls daily. The prematurely born infants of the study are excluded from this discussion. The only infant of the entire group who developed roentgenographic rickets was one of seventeen receiving two teaspoonfuls of cod liver oil daily. A distaste for cod liver oil was noted in this case. It is stated that ten drops of viosterol in oil (2,860 units) was the smallest dose that prevented a fall in both the calcium and the phosphorus of the blood from the first to the later months of the first year of life. This amount is stated as the minimum dose for prophylaxis.

Apparently the lowering of the blood values for calcium and phosphorus represented variations within the normal range, in some instances the later values being slightly less than earlier ones, but still good values. Roentgenographic rickets did not develop in any of six infants receiving one drop of viosterol in oil (286 units) or in any of seven infants receiving one teaspoonful of cod liver oil (approximately 350 units<sup>28</sup>), while rickets was evident in nine of thirty-four control infants.

Hess, Lewis, McLeod and Thomas,<sup>30</sup> 1931: This was an outpatient preventive and curative study of milk from cows fed irradiated yeast and from cows fed irradiated ergosterol. Roentgenograms were used as the criterion. Each variety of milk was produced at levels of 215 and 430 units of vitamin D to the quart and was fed to four groups of infants at a constant level of approximately 24 ounces daily. The vitamin D intake was approximately 160 and 320 units daily. The study group consisted of infants from 1½ to 6 months of age and the observations were made from January to March inclusive. "Thirty-three of the infants had previously been getting cod liver oil, twenty-three of the preventive group and ten of the rachitic group, but this was discontinued, although the amounts were so small as to be inconsequential." The data for the preventive study are not given, but it is stated that rickets was prevented in all infants except two of an unstated number receiving 160 units daily as "yeast milk." Prevention was successful with 160 units as "viosterol milk" in an unstated number of infants, in sixteen infants receiving 320 units as "yeast milk" and in seventeen receiving 320 units as "viosterol milk." The curative study group included thirteen infants; three

in each of the two groups receiving "yeast milk" and two and five infants respectively in the groups receiving 160 and 320 units as "viosterol milk." In two of the three infants receiving 160 units as "yeast milk" the rickets became worse for a period of from one to two months before signs of healing were noted. In all other infants healing was marked or complete at the close of the experiment. No difference is noted between the 160 and the 320 unit "viosterol milk" groups or between either of these groups and the 320 unit "yeast milk" group. Accurate comparison of the relative values of these two varieties of milk does not seem possible. Inferiority of 160 units as "yeast milk" is indicated.

Wyman and Butler,<sup>31</sup> 1932: This was an inpatient curative study of two infants and two children with advanced active rickets. They were kept for a control period of from ten to twenty-three days without antirachitic agents. Serum calcium and phosphorus and roentgenograms were used to determine the amount of healing. During the experimental period the only antirachitic agent used was from 32 to 40 ounces of "yeast milk." The unitage of the milk is not stated, but a succeeding article<sup>32</sup> reports the potency at 430 units to the quart. One of the four subjects showed some small degree of healing in the control period. This child was given pasteurized "yeast milk" and later "yeast milk" boiled for five minutes. The rate of healing was increased over that of the preliminary period. The remaining three children showed evidence of deposition of bone demonstrable by roentgenograms within two weeks of beginning treatment. The authors conclude that "yeast milk" is an effective source of antirachitic substance.

Hess and Lewis,<sup>33</sup> 1932: The study group consisted of ninety-eight infants from 1½ to 6 months of age, mostly Negroes. A few of the babies were in an orphanage, but the majority were outpatients. The study was both preventive and curative and was carried on from January to April. The criterion was roentgenograms. The babies received from 24 to 32 ounces of irradiated milk daily, containing 135 units of vitamin D to the quart. The preventive study concerned thirty-six infants, including one prematurely born, without roentgenographic evidence of rickets at the beginning of the study. Of the remaining sixty-two infants, fourteen had roentgenologic evidence of rickets and forty-eight had clinical signs of rickets without roentgenologic changes. All the infants with roentgenologic evidence of rickets showed signs of healing within from four to six weeks; four of these had not healed completely at the end of the experiment. In the ten cases in which the rickets healed, the average time for healing was fifty-five days. In the discussion of the preventive experiment the authors mention the occurrence of rickets in only the prematurely born baby. The authors conclude that irradiated milk is highly satisfactory both from a prophylactic and from a curative point of view. An examination of the tabular data reveals that in addition to the prematurely born baby, two others (E. H. and P. U.) developed rickets six weeks and two months after the start of the experiment. Because of these two cases the conclusion would seem warranted that irradiated milk was not completely protective against rickets even for full term infants.

Gerstenberger and Horesh,<sup>34</sup> 1932: Two hospitalized rachitic infants were fed 500 cc. daily of vitamin D milk produced by feeding Holstein cows 540,000 units of vitamin D daily as irradiated ergosterol. The unitage of the milk was not stated, but the fat of the milk contained 6.75 units per gram. Assuming that the milk had a fat content of 4 per cent, it may be estimated that the infants received 135 units daily. The vitamin D milk was supplemented with ordinary skimmed milk. These two infants had slight evidences of healing as shown by roentgenograms in three and four weeks respectively, but the process had not healed when the experiment was forced to close after ten and eleven weeks. The blood phosphorus had not reached a normal value in either child by ten weeks. It seems fair to conclude that the level of vitamin D fed approached closely or was below the minimum curative dose.

Mitchell, Eiman, Whipple and Stokes,<sup>35</sup> 1932: This was a study of irradiated milk and milk from irradiated cows, conducted from February to October. The babies were admitted to the study from February to April and each baby was studied from six to eight months. The infants were kept indoors except for three months in the summer, when they were outdoors for two hours daily in a low-roofed, screened pavilion so placed with reference to surrounding buildings that no direct sun touched it and skylight was also excluded. All antirachitic agents were excluded for six weeks before the experiment. The irradiated milk used contained 175 units to the quart as determined by assay of the separated fat. The irradiated milk group consisted of thirteen infants with no roentgenologic evidence of rickets. Roentgenograms were made at regular intervals, but only the final results (October) are recorded. The tabulated data show two children with mild and one child with moderate rickets, all healed. It is stated also that "a small group of markedly rachitic infants have been treated in the ward of the University and Children's Hospitals with irradiated milk as the only antirachitic agent. Prompt healing has occurred in each instance."

The milk from irradiated cows contained 60 units of vitamin D to the quart as determined by assay of the separated fat. The experimental group included twenty infants with no roentgenologic evidence of rickets and one with moderate rickets. The tabulated results of the preventive experiment show three infants with mild and three with moderate rickets, all healed. In the curative experiment the rickets healed, though slowly. The amount of vitamin D received by this group is not stated, but the statement is made that the 95 to 110 units which the youngest babies in the 1932 study of Hess and Lewis must have received is not far in excess of the number of units administered to this group of twenty-one infants. The authors state that the twenty infants of this preventive study were protected.

The authors say: "It is customary in the institution to give from one-half to one teaspoonful of cod liver oil daily and among the older infants and young children the presence of moderate rickets is seen frequently, and severe rickets occasionally." It would be most interesting if this observation were confirmed by a controlled experiment.

On the basis of the data given, the conclusion seems justifiable that neither of the milks studied was completely protective. Evidently rickets developed in both.

groups and was healed by October. The reviewer is leaving out of consideration any possible influence indirect summer sunshine may have had, and the unusually high vitamin D unitage of the irradiated milk.

Barnes,<sup>36</sup> 1933: This was an outpatient curative study, roentgenograms being used as the criterion, in which milk fortified with 400 units of a vitamin D concentrate (Vitex) to the quart was given as the sole antirachitic agent in treating fifteen rachitic infants. The amounts of vitamin D ingested were from 300 to 400 units daily. All the infants recovered promptly. No individual data are given. From this study it may be concluded that cod liver oil concentrate milk with 400 units to the quart will bring about complete healing of rickets under the unrecorded conditions of this experiment.

Hess and Lewis,<sup>37</sup> 1933: This was an outpatient, winter, curative study of irradiated milk, "yeast milk," viosterol in oil and cod liver oil. A large proportion of the infants were Negroes, mostly Puerto Ricans. The babies were from 2 to 17 months of age. Irradiated milk with from 135 to 160 units of vitamin D to the quart was fed at levels of 115 and 75 units (24 and 16 ounces of milk). The criterion was roentgenograms. The 115 unit group included four infants of 17, 13, 9 and 4 months of age. The three older infants had severe rickets, and after four weeks of feeding with irradiated milk the healing was recorded as 3 plus and 2 plus. The youngest infant had slight rickets and the healing was recorded as 1 plus. The 75 unit group included six infants of 9, 9, 6, 4, 3 and 2½ months of age. The 6 months old infants had marked rickets and the healing was questionable. One 9 months old infant had moderate rickets and the healing was 1½ plus. The remaining infants had slight rickets and the healing after four weeks was 2, 1½, 1 and 1 plus.

In the study of "yeast milk" two groups of five infants each were given 24 ounces daily of milk containing 325 and 215 units of vitamin D to the quart respectively. The two groups received 245 and 160 units daily respectively. The five infants of the 245 unit group were 8, 6, 5, 6 and 4 months of age. At the start the rickets was moderate in three and slight to moderate in two infants. After four weeks the healing was 2½, 2, 1½, 1 and 1 plus. The infants of the 160 unit group were 11, 5, 6, 5 and 6 months of age. At the start the rickets was moderate in two, slight to moderate in one and slight in two. After four weeks the healing was 2, 2, 1, 1½ plus and 0. Healing was present in six weeks in the baby who showed no healing at four weeks.

In the study of viosterol preparations eight babies from 2 to 12 months of age were given 865 units daily (as viosterol in oil). The amount of milk is not stated. On the assumption that the amount of milk was the same as for most of the associated observations, viosterol showed a distinct inferiority as compared with irradiated milk and "yeast milk." The 865 units as viosterol permitted one-third as much healing as did 115 units as irradiated milk and one-half as much as 160 units as "yeast milk."

The results with cod liver oil were discarded by the authors because they were irregular and unsatisfactory. The authors concluded that irradiated milk has about twice the effectiveness of "yeast milk" and fifteen times the effectiveness of viosterol on the basis of equal unitage. Their conclusions otherwise, as based on the data presented, cannot be determined for the reason

that the discussion of the vitamin D situation is based on all the previous experience of these authors.

From the data presented it is obvious that irradiated milk with from 135 to 160 units to the quart produces improvement in rickets. A valid comparison between the 75 unit irradiated milk group and the other groups is difficult for the reason that the milk intake of the 75 unit group was reduced in proportion to the vitamin D reduction. When the healing results are averaged, only a slight advantage is evident in favor of the larger over the smaller unitage of "yeast milk," the difference between 1.3 and 1.6 plus. When the 115 unit irradiated milk group is compared with the 160 unit "yeast milk" group, there appears to be two-thirds as much healing in the "yeast milk" group with four-thirds the amount of vitamin D. Thus it may be considered that for these two groups of babies irradiated milk seems approximately twice as effective as "yeast milk." It may be concluded also that 24 ounces of "yeast milk" containing either 215 or 325 units of vitamin D to the quart produces improvement in rachitic infants, the latter being somewhat more effective.

In this and other publications by these authors, comparisons are made between the various antirachitic agents as regards relative effectiveness for man. Among the agents compared is cod liver oil. These comparisons, especially of irradiated milk with cod liver oil, have been quoted extensively. For comparison it would seem desirable that the values to be compared be determined with some degree of accuracy. So far as the reviewer can ascertain, these authors have determined neither the minimum protective nor the minimum curative dose of cod liver oil, but a value has been assigned to this substance and the assumed value has been used for comparison. If actual data available from other sources indicate conclusions at variance with those of these authors as regards cod liver oil, it seems appropriate to give preference to the conclusions based on data.

Wyman,<sup>38</sup> 1933: This was a metabolic study of a 16½ months old rachitic infant who was given "yeast milk" containing 430 units of vitamin D to the quart in amounts of from 940 to 1,180 cc. (430 to 540 units) daily. The control period was in April and the experimental period from April 23 to June 9. The serum calcium and phosphorus at the end of the control period were 9.7 and 2.4 mg. per hundred cubic centimeters respectively; after twelve days of the experimental period the values became 11.8 and 5.5 mg. respectively. The retentions of calcium and phosphorus in the control period were 0.078 and 0.020 Gm. daily, and during the experimental period 0.855 and 0.592 Gm. These results indicate that "yeast milk" with 430 units of vitamin D to the quart allows ample for good healing of rickets when the infant receives a quart or more of milk. The increase in serum calcium and phosphorus is very satisfactory for the time allowed. The retention indicates rapid deposition of calcium.

Kramer and Gittleman,<sup>38</sup> 1933: This was an inpatient curative study comparing irradiated milk and milk from cows fed irradiated yeast. The criteria consisted of roentgenograms and determinations of the calcium and phosphorus of the serum. The study was carried into early summer. Most of the infants were Negroes; all were housed in such a manner as to minimize the effect of sunshine, and the results with control patients indicated a negligible effect from extraneous vitamin D

36. Barnes, D. J.: *J. Michigan State M. Soc.* 32:242 (April) 1933.  
37. Hess, A. F., and Lewis, J. M.: *An Appraisal of Antirachitics in Terms of Rat and Clinical Units*, *J. A. M. A.* 101:181 (July 15) 1933.

38. Kramer, Benjamin, and Gittleman, J. F.: *New England J. Med.* 209:906 (Nov. 2) 1933.

factors. Thirteen infants from 3 to 22 months of age were chosen as subjects and were kept without antirachitic treatment for a period to preclude spontaneous healing. Three infants showed evidence of healing in the preliminary period. The remaining ten infants were used for the experiment. Each infant ingested 1 quart of milk daily. Two infants received "yeast milk" containing 150 units; three received "yeast milk" containing 110; three received irradiated milk at the 150 unit and two at the 110 unit level. At the levels fed, the authors observed no significant difference in effectiveness between "yeast milk" and irradiated milk.

This was a well controlled experiment. Whether significant or not, it is of interest to note the ratios of effectiveness as determined by the time required to produce the first signs of healing by roentgen rays. At each level the irradiated milk showed a slight superiority over the "yeast milk." For the 150 unit groups the ratio was 1:1.4 and for the 110 unit groups 1:1.45. At the same time the expected differences appear between 110 and 150 units of each group. The 110 unit irradiated milk produced approximately the same initial healing results as the 150 unit "yeast milk." The experiment was not continued to complete healing, though the healing was far advanced in those cases in which it was not complete. The blood calcium and phosphorus values were not yet normal in some of the infants at the close of the experiment. Failure to produce normal values after from one to one and one-half months of treatment indicates a relatively low degree of effectiveness.

Jeans and Stearns,<sup>39</sup> 1934: This was an inpatient, metabolic, preventive study. The study group included seven infants from 3 weeks to 15 months of age. Irradiated evaporated milk, evaporated milk with cod liver oil concentrate (Vitex or Zucker concentrate) and evaporated milk together with cod liver oil given separately were the three diets used for the observations. Food intakes were known accurately. Each of the three experimental diets was given to a group of infants of the same age and milk intake; in the course of the observations, each infant received each diet in turn. The criteria used were calcium retention, rates of growth, roentgenograms and serum calcium and phosphorus. The study included forty metabolic periods. The youngest infants received only 60 units of vitamin D daily at the beginning of the study; by 16 weeks of age all the infants were receiving 135 units daily. During the study, no infant developed rickets. The calcium retentions on the three diets showed the same range. No source of vitamin D proved superior in any way to either of the other two as regards retentions. The average calcium retention of the group was lower by 10 mg. per kilogram than the retention observed with infants given the same milk intakes per kilogram but 340 units of vitamin D as cod liver oil. The growth and development of the study group was definitely slower than in control groups given 340 units of vitamin D. The authors conclude that the three sources of vitamin D studied are apparently equivalent, unit for unit. It is implied also that 135 units of vitamin D to the quart of reconstituted evaporated milk does not allow sufficient intake of vitamin D to permit the best development of infants, even though it is indicated that this amount of vitamin D will prevent rickets.

Wilson,<sup>40</sup> 1934: This was a clinical outpatient study of cod liver oil concentrate (Vitex) milk containing

400 units to the quart. The study group consisted of thirty-three infants from 6 to 13 weeks of age at the start, including two pairs of twins, three prematurely born and one infant probably born prematurely. With one exception, none had had antirachitic treatment before the test period. The feeding was undiluted milk with from 8 to 10 per cent added sugar. The milk ingestion varied from 17 to 32 ounces daily (215 to 400 units). The criteria consisted of monthly roentgenograms and body weights and lengths. The progress and general development of the infants were generally normal and satisfactory. All had attained at least the average length and weight for their ages before the end of the study. Musculature and appearance were excellent. Some of the infants developed what is termed mild or doubtful rickets; for the purpose of this review and for reasons stated in the preceding discussion, these cases are classed as normal. Two infants developed rickets of moderate and significant severity. One of these two infants was "probably premature." Prematurity might be a partial explanation of the result even though the regimen prevented rickets in three other babies prematurely born and in two pairs of twins. The other rachitic infant developed rickets in a home with such poor conditions that removal from the home became desirable; it recovered from rickets very promptly after removal while receiving vitamin D milk as the only antirachitic agent. The rapid recovery suggests strongly that the previous intake of vitamin D milk may have been different from that which was assumed. Accepting these two cases of rickets at their face value, the study shows that cod liver oil concentrate milk containing 400 units of vitamin D to the quart prevented rickets in twenty-eight of twenty-nine full term infants and in three of four infants prematurely born. The rapid recovery of the one full term infant from rickets after it was brought under better control favors holding in abeyance the full acceptance of this case.

Drake, Tisdall and Brown,<sup>41</sup> 1934: This was an outpatient preventive study carried on from October to May. It concerned the effects of cod liver oil, viosterol and irradiated milk. Roentgenograms were the criterion. Growth in weight was reported as normal, and above or below normal. A group of 137 infants received cod liver oil; one infant receiving two teaspoonfuls (700 units) and two receiving three teaspoonfuls (1,050 units) developed moderate or marked rickets; none receiving one teaspoonful (350 units) developed this degree of rickets. A group of 186 infants received from 270 to 2,160 units of vitamin D as viosterol in oil. Of these no infant developed moderate or marked rickets at any level fed. A group of 141 infants received irradiated milk. None developed moderate or marked rickets. Thirty-eight of these infants under 4 months of age at the beginning of the experiment received 20 ounces of milk (95 units). The absence of moderate rickets in this group is contrasted with observations on thirty-one untreated infants, four of whom developed moderate or marked rickets. The authors do not draw any comparative conclusions concerning the relative values of the various sources of vitamin D, nor do such comparisons seem possible because the three types employed were not given in similar unitage. No distinction is made between babies breast fed and those artificially fed except in the irradiated milk group. Some of the infants received egg yolk. This study is illustrative of the weaknesses

inherent in outpatient studies in general. One might infer that 95 units as irradiated milk is superior to 1,050 units as cod liver oil, though such an inference is invalidated by the results with 350 units as cod liver oil. A reasonable conclusion is that irradiated milk was apparently effective in preventing rickets, as was also cod liver oil in the amount of one teaspoonful daily (350 units) and viosterol in oil at the level of 270 units daily.

Barnes,<sup>42</sup> 1934: This was an outpatient preventive and curative study conducted from November to April. The study groups included twenty-two white and ten Negro infants without rickets and four white and two Negro infants with mild rickets. The infants varied in age from 1½ to 12 months, the average age at the start being about 6 months. No infant had had any antirachitic therapy except casual exposure to the sun during the preceding summer. During the experiment each infant, regardless of the total milk intake, received 135 units of vitamin D as cod liver oil concentrate (Vitex) in milk. Biweekly weights and roentgenograms were the criteria. A group of twenty-five infants, twelve white and thirteen Negroes, served as controls; these had had no antirachitic therapy through the winter and had a roentgenologic examination in April. The average age of the controls in April was 6.2 months. Fourteen (56 per cent) of the control group were rachitic as determined by the x-rays. Of the experimental groups the thirty-two normal infants were completely protected; the weight gains were satisfactory. The six infants who showed slight signs of rickets at the beginning of the experiment showed progressive improvement. In no case did the patient grow worse during the study. Healing occurred in from eight to sixteen weeks. On the basis of these observations it may be concluded that cod liver oil concentrate milk will prevent and cure rickets when the amounts of milk are adequate and the vitamin D intake is maintained at a constant level of 135 units daily. The slow healing of rickets suggests that this level approaches the minimal effective amount.

Wyman, Eley, Bunker and Harris,<sup>43</sup> 1935: This was an inpatient, curative study conducted from January to March, comparing irradiated milk and milk from cows fed irradiated yeast. The irradiated milk averaged barely 135 units and the "yeast milk" varied from 160 to 175 units to the quart. Roentgenograms and determinations of serum calcium and phosphorus were made at weekly intervals. The six infants observed were kept without vitamin D for a preliminary period to preclude spontaneous healing. Three infants, 6, 7 and 26 months of age, were given irradiated milk and three infants, 8, 9 and 22 months of age, were given "yeast milk," both milks in daily amounts of from 26 to 32 ounces. Each infant showed some healing within four weeks; they were not studied to complete healing. From examination of the roentgenograms and the rate of increase of the calcium × phosphorus product the authors conclude that the two milks are equivalent, unit for unit.

In this experiment the "yeast milk" contained from 20 to 30 per cent more vitamin D to the quart than did the irradiated milk, and the babies of the "yeast milk" group received approximately 20 per cent more vitamin D than did the babies of the irradiated milk group. Despite this disparity in the amounts of vitamin D the blood phosphorus curves, when plotted against time, showed a much steeper rise for the irradiated milk

group. The comparison obviously indicates a superiority for irradiated milk. The superiority is something more than 20 per cent.

Gerstenberger, Horesh, Van Horn, Krauss and Bethke,<sup>44</sup> 1935: This was an inpatient, curative study of irradiated milk and milk from cows fed irradiated yeast. The criteria used were roentgenograms, the time required for complete healing, and the serum calcium, inorganic phosphorus and phosphatase. It was originally intended to have the two milks at the same unitage level of vitamin D; viz., 148 units to the quart. The preliminary assays indicated an equal unitage, but later check assays showed a content of 216 units to the quart for the irradiated milk and 148 units for the "yeast milk," a ratio of approximately 1.5:1. In the clinical trial thirteen rachitic infants (twelve Negro, one white) were kept for from two to four weeks without antirachitic treatment to preclude spontaneous healing. Irradiated and "yeast" milks were then fed at levels of 720 and 480 cc., the total milk intake being kept approximately the same by the addition of skimmed milk to the diet. Both levels of feeding produced healing of rickets, the lower level much more slowly than the higher. From a comparison, in infants of the same age and severity of rickets, of the times required for healing as judged by roentgenograms and the production of normal blood values, the authors estimate that the irradiated milk was one and one-half times as potent as the "yeast milk." This ratio is the same as that found by assay of the milks. The authors conclude that the two types of milk seem of equal efficacy, unit for unit, for healing rickets in infants. They express the opinion that, if some difference does exist, it is the irradiated milk that is slightly superior. The belief is stated that 75 units of vitamin D daily is very close to the minimal amount required for ultimate healing of active rickets. In this experiment, vitamin D in the amount of 110 units daily was sufficient to heal rickets in from nine to twelve weeks and to produce normal serum calcium and phosphorus values in from seven to nine weeks.

This study is a good example of a well controlled curative experiment. The authors present a critical discussion of criteria for this type of study and offer an explanation of the lack of agreement between the results presented and some of those previously published by others. Some data are given as the basis of a discussion of the minimum preventive and curative dose of cod liver oil. In comparing irradiated milk to cod liver oil, the authors state that their data would probably establish the ratio at 1:1.

The data presented in this publication permit interpretations in addition to those presented. When the time for bone healing is used as the criterion, no difference is established between the 108 unit irradiated milk and the 108 unit "yeast milk" groups or between the 108 unit irradiated milk and the 162 unit irradiated milk groups. When the time required to establish normal blood values is used as the criterion, definite differences are observed. Irradiated milk supplying 108 units seems superior to "yeast milk" supplying 103 units, and the irradiated milk supplying 162 units seems superior to irradiated milk supplying 108 units. When the time required to establish normal blood calcium and phosphorus values is used as the criterion, the ratio of effectiveness of irradiated milk as compared to "yeast milk" is 1:1.3; when phosphatase values are used the ratio is 1:1.4. From the point of view here presented,

the author's opinion as to the possible superiority of irradiated milk seems confirmed.

Lewis,<sup>45</sup> 1935: Observations are reported which compare irradiated ergosterol in corn oil with irradiated ergosterol in milk. The preparation used was "crystalline vitamin D (calciferol)." This was an outpatient curative study. The study group included thirty-six infants, divided into four groups. Nine infants received 243 units of this vitamin D in oil, ten received 2,430 units in oil, nine received 243 units in milk and eight received 121 units in milk. Each baby received 24 ounces of milk daily. The criterion was the amount of healing at four, six and eight weeks as shown by roentgenograms. The author concluded that better results were obtained with 121 units in milk than with 243 units in oil and that 243 units in milk gave better results than 2,430 units in oil. He believes that the results obtained offer an explanation for the greater effectiveness of antirachitic milks as compared with viosterol in oil. Irradiated ergosterol in the amount of 121 units in milk was below the minimum curative level, as was also 243 units in oil. However, 243 units in milk was an adequate curative dose; this amount approximates three times the amount the author believes effective when administered as irradiated milk.

Tisdall, Drake and Brown,<sup>46</sup> 1935: Two infants with acute rickets were treated with irradiated cholesterol in corn oil. This substance in the amount of 750 units daily produced rapid healing. Good deposition of new bone was observed in two weeks and complete cure by seven weeks.

Rapoport, Stokes and Whipple,<sup>47</sup> 1935: This was an inpatient preventive and curative study of irradiated evaporated milk containing 125 units of vitamin D to the 14½ ounce can. The study group consisted of twenty-three infants under 5 months of age at the beginning of the experiment. The study was conducted from January 2 to May 15. Five infants had mild rickets at the beginning of the study. All the infants were fed nonirradiated evaporated milk for about one month. They were then divided into two groups according to the presence or absence of rickets by roentgenographic examination. The preventive group comprised nine infants and the curative group thirteen. One infant is considered separately because he failed to develop rickets after twelve weeks of feeding with nonirradiated milk that contained 30 units of vitamin D to the 14½ ounce can.

The nine infants of the preventive group received amounts of milk which permitted the ingestion of from 88 to 127 units of vitamin D daily. One developed mild rickets after eight weeks of irradiated milk feeding; the rickets healed in another four weeks. One infant developed moderate rickets, which later began to heal under the same regimen. The latter infant was one of twins and weighed 6 pounds 13 ounces (3,091 Gm.) at 5 weeks of age when the experiment started. He was then given nonirradiated milk for eight weeks without the development of rickets. With the irradiated milk he received 92 units of vitamin D daily. For the entire group the duration of irradiated milk feeding varied from four and one-half to thirteen weeks.

Of the thirteen infants in the curative experiment, two had complete healing, three slight healing, two an

advance of the rachitic process followed by slight healing, four no healing and two an advance of the process without healing.

The authors conclude that irradiated evaporated milk containing 125 units of vitamin D to the 14½ ounce can appeared to be adequate for the prevention of rickets in infants. They conclude also that the same milk appears to be unreliable for the cure of rickets in infants.

The results with two of the babies in the preventive group raise a question as to the adequacy of the protection provided by the product used. At least it is indicated that the amount of vitamin D given approaches the lowest level of a preventive dose. The curative results are in distinct contrast to those of other studies of this review. The fact that rickets increased in severity in 30 per cent of the infants of the curative study indicates a low preventive effectiveness.

Jeans and Stearns,<sup>48</sup> 1935: This was an inpatient, winter, metabolic study. The study group consisted of five white infants. When the experiment was started, one infant was 11 weeks, one was 6 weeks and the remaining three were from 10 to 20 days old. They were given evaporated milk containing cod liver oil concentrate (Vitex) with 400 units to the reconstituted quart. The daily intake of vitamin D varied from 245 to 400 units. The rate of growth of each infant both in weight and in length was above the Kornfeld averages and equal to the rate of growth of infants kept under similar conditions but given 340 units of vitamin D as cod liver oil. The infants were precocious in dentition and muscular achievement. The roentgenograms showed no rickets. The per kilogram retentions of calcium for thirty-four metabolism periods were reported. The retention for each intake was within the range and averaged approximately the same as the retention of a larger group of infants (200 periods of study) given 340 units of vitamin D daily as cod liver oil, and about 10 mg. per kilogram higher than the retentions observed in a similar group of infants given 135 unit milk. From this study it was concluded that evaporated milk containing cod liver oil concentrate sufficient to allow 400 units of vitamin D to the reconstituted quart prevents the development of rickets and permits high retentions of calcium and excellent growth and development of infants.

Strong, Naef and Harper,<sup>49</sup> 1935: This was an outpatient, preventive study carried on in New Orleans from December 1933 to November 1934. The study group consisted of twenty-two infants who were fed irradiated evaporated milk in such quantities that from 70 to 160 units of vitamin D was ingested daily, the amount being proportionate to the age of the infant. The infants were mostly in the first six months of life. The results were determined by roentgenograms, a single examination being made for each baby after a period of observation of from four to seven months. Roentgenograms were not made of two of the twenty-two infants. Of the remaining twenty infants the roentgenograms were made as follows: one in April, three in May, twelve in June, one in July, two in August and one in October. One baby examined in August was reexamined in November. Slight evidence of rickets was present in two infants, one examined in April and one in June. A control group given from 10 to 15 drops of viosterol daily (from 865 to 1,300 units) had no evidence of rickets. The authors con-

clude that irradiated evaporated milk should be supplemented with additional vitamin D. Presumably they held the slight amount of rickets found as of significance. A preventive study in the summer can be of no significance if rickets is not found. The finding of definite rickets would be important. The question arises as to how definite the rickets was in these two cases.

Compere, Porter and Roberts,<sup>50</sup> 1935: This was an inpatient curative study of irradiated yeast in comparison with cod liver oil. It was conducted from January 1 to April 1. The study group consisted of twenty-one infants from 5 months to 2½ years of age. The infants were divided into five groups. Group 1 served as the control and group 2 received 2,061 units of vitamin D as cod liver oil. The remaining groups received irradiated yeast in amounts which supplied 2,252, 6,755 and 13,511 units of vitamin D. Roentgenograms were taken and determinations of calcium and phosphorus in the serum were made. The authors conclude that from 1.1 to 3.3 times as much of the vitamin D of irradiated yeast as of the vitamin D of cod liver oil is needed to produce the same curative results as determined by roentgenograms.

The reviewer is unable to evaluate this study on any basis employed in this review. More than half of the babies apparently had rickets of the mild and doubtful variety, which has been excluded from consideration in this review. Even by the exacting criteria employed, one baby had "little evidence of rickets." Further difficulties in evaluation are encountered in that the dosages employed are far above what are generally considered to be minimum effective levels.

Peterman and Epstein,<sup>51</sup> 1935: This was an orphanage study of evaporated milk containing 400 units of vitamin D as cod liver oil concentrate (Barthen) to the 14½ ounce can (13 fluidounces). The observations began in January 1934 and continued to February 1935. As infants were discharged from the study group, replacements were made. The babies ranged in age from 2½ to 18 months at the beginning of the study. The criteria were roentgenograms and calcium and phosphorus values of the serum. The lowest average daily intake of vitamin D for any baby for any tabulated period was 308 units and the highest was 620 units. The authors found that no infant had any clinical, chemical or roentgenographic sign of rickets during the period of the study, and they concluded that the milk was amply protective.

From the tabulated data it may be calculated that the twelve babies with which the experiment started in January had at the beginning an average of 9.10 mg. of calcium and 6.08 mg. of phosphorus per hundred cubic centimeters of serum. In April, approximately three months after the experiment started, the average values for the same babies were calcium 10.12 mg. and phosphorus 3.54 mg. per hundred cubic centimeters. In February 1935 the average values for all the babies remaining in the group (ten infants) were calcium 10.35 mg. and phosphorus 4.74 mg. per hundred cubic centimeters. Such results can scarcely be considered satisfactory. The April values are such as might be expected with little or no vitamin D and are distinctly at variance with those of other studies of this review in which an equivalent or smaller quantity of vitamin D was used as cod liver oil or cod liver oil concentrate.

Drake, Tisdall and Brown,<sup>52</sup> 1936: This was an outpatient winter study of 103 infants from 1 to 6 months of age who received irradiated evaporated milk. The milk contained 9.8 units of vitamin D to the ounce. The amount of milk received by the babies varied from 6 to 20 ounces. Few babies received more than 16 ounces. Moderate or marked rickets was not observed; 17 per cent developed mild rickets. Of fifty-two babies receiving evaporated milk without vitamin D, 10 per cent developed moderate or marked rickets and 29 per cent developed mild rickets. Of fifty-two babies receiving pasteurized fresh milk without vitamin D, 23 per cent developed moderate or marked rickets and 25 per cent developed mild rickets. Concerning the slight and mild rickets, the authors state: "In the interpretation of the x-ray from the clinical standpoint it must be kept in mind that the 'extremely slight rickets' are so slight that most physicians would classify these x-ray plates as normal. Those grouped as 'mild rickets' also do not show changes which would cause any great concern from the clinical standpoint." For the purpose of this review the cases of mild rickets are excluded from consideration. The authors state that the babies gained weight faster than the usual rate. Growth data are not given.

Rapaport and Stokes,<sup>53</sup> 1936: This was an inpatient winter study of ten infants receiving irradiated evaporated milk and of nine infants receiving irradiated fresh milk. For eighteen of the infants the experiment was preventive and for one curative. At the beginning of the experiment the infants were from 2 weeks to 5½ months of age, with an average age of 2 months. The evaporated milk contained 125 units of vitamin D to the 14½ ounce can and the fresh milk 140 units to the quart. For both groups of infants the vitamin D intake varied from 100 to 145 units daily. The observations were made over a period of four and one-half months. No infant developed rickets. The one infant who had mild rickets at the beginning of the study had slow healing; healing was first noted at thirteen weeks and was complete at eighteen weeks. The authors call attention to the lack of agreement between the clinical and the x-ray signs of rickets. It is stated that excellent growth and development of the infants were observed.

The results of this experiment indicate that irradiated fresh milk and irradiated evaporated milk are of equal value. The slow healing of rickets indicates a close approach to a minimum effective level of vitamin D. As nearly as can be determined from the data given, the rates of growth correspond closely to Kornfeld's averages with the exception of two babies who made greater growth progress.

Lewis,<sup>54</sup> 1936: This report concerns the effect of crystalline vitamin D administered in milk, in oil and in propylene glycol, in an outpatient preventive study conducted from December to the end of April. The 255 infants were distributed into eight groups. Between 50 and 60 per cent of the babies of each group were Negroes. Nearly 50 per cent of the babies were either partially or wholly breast fed, but none of these were included in the groups receiving the vitamin D in milk.

Rickets developed in three of fifty-eight babies (5.1 per cent) receiving 145 units of vitamin D in 28 ounces of milk, in six of forty-one infants (14.6 per cent) receiving 145 units of vitamin D in oil, and in six of forty-four infants (13.6 per cent) receiving the same

50. Compere, E. L.; Porter, Thelma E., and Roberts, Lydia J.: A Clinical Comparison of the Antirachitic Value of Irradiated Yeast and of Cod Liver Oil. *Am. J. Dis. Child.* 50: 55 (July) 1935.

52. Drake, T. G. H.; Tisdall, F. F., and Brown, A. G.: *J. Pediat.* 8: 161 (Feb.) 1936.

53. Rapaport, Milton, and Stokes, J., Jr.: *J. Pediat.* 8: 154 (Feb.) 1936.

54. Lewis, J. M.: *J. Pediat.* 8: 308 (March) 1936.

amount of vitamin D in propylene glycol. At the level of 290 units of vitamin D daily, rickets developed in one of fifty-one infants (1.9 per cent), in five of fifty-two infants (9.6 per cent) and in five of forty-five infants (11.1 per cent) who received the vitamin D respectively in milk, in oil and in propylene glycol. Of forty-two babies who received 1,450 units in oil, one (2.4 per cent) developed rickets. Of a control group of twenty-two babies receiving no vitamin D, eight (36.3 per cent) developed rickets. In a baby with rickets 290 units of crystalline vitamin D in 28 ounces of milk was effective, whereas previously in the same infant 290 units in a teaspoonful of milk produced no healing.

The author concluded that "crystalline vitamin D" is much more effective when dispersed in milk than when administered in a more concentrated state in oil or propylene glycol. He considers also that 1,450 units in oil is a satisfactory protective dose. Interpretation of this study is not aided by the fact that in a preventive experiment rickets developed at all levels of vitamin D administration and that an intake of vitamin D which permits rickets is considered satisfactory.

#### SUMMARY OF CLINICAL STUDIES

*Cod Liver Oil.*—DeSanctis and Craig found that cod liver oil at an estimated level of from 380 to 460 units prevented physical signs of rickets in 97 per cent of the babies studied. Barnes, Brady and James observed cure or prevention of rickets in all but two of sixty-four babies receiving 840 units of vitamin D as cod liver oil in an outpatient study; the mother of one of the rachitic infants was noncooperative. Also, in an outpatient study Drake, Tisdall and Brown obtained complete protection against moderate rickets with one teaspoonful of cod liver oil (350 units) daily, though complete protection was not attained with two and three times this amount. Julius Hess observed no rickets when one teaspoonful of cod liver oil (350 units) was fed daily. Jeans and Stearns<sup>22</sup> and Nelson<sup>23</sup> observed ample retentions of calcium and phosphorus and no rickets when one teaspoonful of cod liver oil was given. Jeans and Stearns found poorer retentions of calcium and phosphorus, though no rickets, with from 60 to 135 units of vitamin D as cod liver oil. The evidence presented can be interpreted to indicate that one standard teaspoonful of cod liver oil (350 units) is ample and that 135 units or less may prevent rickets, but it permits retentions of calcium and phosphorus definitely lower than the retentions obtained with a larger intake of vitamin D.

*Irradiated Ergosterol.*—The lowest level of irradiated ergosterol found successful in preventing rickets is 270 units, as reported by Drake, Tisdall and Brown, and 286 units as reported by Julius Hess. This is in contrast to the failure of Barnes to prevent rickets with 750 units and the failure of Alfred Hess to prevent rickets with 5,700 units: however, in the same experiment Hess observed rickets prevention with 2,860 units. Later, Alfred Hess obtained healing with 865 units. Lewis found 243 units as crystalline vitamin D in oil below the minimum curative level and later found 290 units in either propylene glycol or in oil to be below the minimum protective level. The data cited are too conflicting to allow satisfactory conclusions. If 270 units (Drake, Tisdall and Brown) daily is an adequate preventive dose, it may be considered that the minimum preventive dose has not yet been determined.

*Cod Liver Oil Concentrate in Milk.*—Using milk containing vitamin D as cod liver oil concentrate in the

amount of 400 units to the quart, Barnes found that from 300 to 400 units brought about prompt recovery from rickets. Later he found that 135 units daily in milk gave complete protection against rickets and produced slow but complete healing of rickets. Wilson obtained protection against moderate rickets with 400 unit milk in all full term infants studied except one not under good control. The experiments cited are with fresh milk. It may be concluded that fresh milk containing 400 units of cod liver oil concentrate to the quart when fed in customary amounts to full term infants will prevent rickets.

Evaporated milk with cod liver oil concentrate has produced results similar to those observed with fresh milk, with the exception of Peterman and Epstein's study. Jeans and Stearns observed not only prevention of rickets but high retentions of calcium and phosphorus when evaporated milk was fed with 400 units to the reconstituted quart. The retentions were of the same order as those observed when one teaspoonful of cod liver oil was given and considerably better than the retentions obtained with 135 unit milk. The retentions with 135 unit milk were believed to be suboptimal.

The results with fresh milk and with evaporated milk are sufficiently similar to permit their consideration as of one group. Though 135 unit milk prevents rickets, it may permit a suboptimal intake of vitamin D as judged by calcium retention. Milk containing 400 units to the quart seems entirely adequate.

*Irradiated Milk.*—Four preventive studies of irradiated fresh milk have been reported. In all four reports good results are claimed, but failure in complete prevention is recorded for two of the four studies.

The results with irradiated evaporated milk agree with those of irradiated fresh milk. In the study of Rapoport, Stokes and Whipple, rickets appeared in one or two of the nine subjects observed, and in the curative study rickets increased in severity in several cases. In the 1936 report of Rapoport and Stokes, better results are recorded. Drake, Tisdall and Brown report the prevention of moderate rickets. Two of twenty-two infants of Strong's study developed rickets. Jeans and Stearns report what are considered to be suboptimal retention of calcium with irradiated evaporated milk.

No reason has become evident for considering that irradiated fresh milk and irradiated evaporated milk have different antirachitic values. In the recent study of Rapoport and Stokes the two varieties were compared under the same conditions and appeared to be of similar value. In curative experiments with irradiated milk additional evidence is offered that vitamin D is present in amounts very close to the minimum effective level. The time required for healing is long and in some instances no healing occurred.

It may be concluded that irradiated milk will prevent rickets in most full term babies but that the amount of vitamin D present approaches closely the minimum preventive level and permits what is believed to be suboptimal retention of calcium.

*"Yeast Milk."*—Only one preventive study with "yeast milk" has been found (Hess, 1931). In this study rickets developed at a level of 160 units daily and was prevented at a level of 320 units. In this study two of the three babies observed on a curative basis had an increase in their rickets at the 160 unit level. In contrast to this curative observation, Kramer obtained healing at a level of 150 units and Gerstenberger at a level of 74 units. Wyman's studies show excellent antirachitic values for "yeast milk" with 430 units to the quart when a quart or more of milk is ingested.

*Irradiated Ergosterol Milk.*—Using milk from cows fed irradiated ergosterol preparations, Hess observed prevention of rickets with 160 and with 320 units daily. Gerstenberger observed slow and uncertain curative results with milk containing approximately 135 units to the quart. When crystalline vitamin D was added directly to milk, Lewis found 121 units daily to be below the minimum curative level and 243 units an adequate curative dose; later he found 290 units in milk to be a more or less adequate protective level. If 121 units daily is below the minimum curative level, an inferiority to irradiated milk and cod liver oil concentrate milk is indicated.

*Animal Source Group.*—Only three reports have been found in which two sources of vitamin D of animal origin are compared by use concomitantly in the same experiment. One of these (Daniels) may be disregarded because of unknown potency of the materials used. The study of Drake, Tisdall and Brown offers no basis for comparison. Cod liver oil at the lowest level fed, viz., one teaspoonful, protected against rickets. Irradiated milk fed at levels permitting 95 or more units daily gave protection. Jeans and Stearns compared cod liver oil, cod liver oil concentrate milk and irradiated milk with the conclusion that these are of equal value, unit for unit when the criterion is calcium retention.

Indirect comparisons also indicate equal values. Barnes prevented rickets with 135 units as cod liver oil concentrate in milk, and in several studies rickets was almost completely prevented with 135 unit irradiated milk.

Such evidence as is available may be interpreted to show that cod liver oil, cod liver oil concentrate milk and irradiated milk are of equal potency for the human being, unit for unit.

*Vegetable Source Group.*—Hess is the only one who has compared two sources of vitamin D of vegetable origin in the same experiment. He found 160 units as irradiated ergosterol milk to be protective whereas 160 units as "yeast milk" was not. He also found irradiated ergosterol in oil inferior to "yeast milk," the requirement for viosterol being ten times that for "yeast milk." Lewis reported the requirement of crystalline vitamin D in oil to be ten times that of crystalline vitamin D added to milk; the data of a later experiment indicate that the requirement for the crystalline vitamin D in oil is less than five times that for the crystalline vitamin D in milk; the minimum protective dose was not determined.

The comparisons cited between viosterol in oil and the vitamin D milks do not receive full support from studies of viosterol made by others. For example, the protection against rickets obtained by Drake, Tisdall and Brown with 270 units and by Julius Hess with 286 units as viosterol in oil is in striking contrast to the results reported by Alfred Hess and Lewis.

On the basis of Alfred Hess's report, an advantage might be interpreted in favor of irradiated ergosterol milk over "yeast milk." However, Kramer obtained curative results with 150 units as "yeast milk." The evidence available does not indicate any essential difference in relative human value between yeast milk and irradiated ergosterol milk.

*Animal versus Vegetable Sources.*—The reports of Barnes and DeSanctis indicate a superiority of cod liver oil over viosterol. The reports of Alfred Hess, of Kramer and of Gerstenberger and his associates may be interpreted to indicate that irradiated milk is from

1.3 to 2 times the value of "yeast milk." The report of Wyman indicates that irradiated milk is more than 20 per cent superior to "yeast milk" on a unit for unit basis.

On the basis that, unit for unit, yeast milk and irradiated ergosterol milk are of the same value, that irradiated milk and cod liver oil concentrate milk are of the same value, and that irradiated milk is superior to yeast milk, a group relationship has been established. Even granting these premises, the exact relationship between the two groups is not accurately determined. Whatever the difference, it seems to be small. On the basis of the evidence reviewed and its evaluation, the difference probably is not more than 1.5:1. This ratio of effectiveness is based entirely on curative experiments. Because of the possible inherent weaknesses already discussed for curative studies, corroboration by preventive experiments seems highly desirable.

*Dispersion of Vitamin D in Milk.*—The report of Lewis that crystalline vitamin D is of greater value in milk than in oil raises a new question for consideration. If the enhanced value is due to dispersion and consequent increased availability for utilization, all the vitamin D milks have this factor in common. Observations recorded in this review indicate that cod liver oil and cod liver oil concentrate in milk are of equal value. In Lewis's experiment 243 units of vitamin D in milk was amply effective in a curative experiment, while the same amount in oil was quite ineffective. In a later report 290 units in milk was relatively effective in a preventive experiment, whereas the same amount in propylene glycol or in oil seemed less effective. These observations may be contrasted with the observation of Drake, Tisdall and Brown that 270 units in oil seemed amply protective. As regards animal experiments, Haman and Steenbock<sup>7</sup> were unable to observe any difference in the chicken between irradiated ergosterol in oil and irradiated ergosterol in milk.

#### SUMMARY

Exclusive of purely laboratory products there may be only two varieties of vitamin D, one of animal origin and one of vegetable origin. All animal sources may have a vitamin D of the same value. The same is true for all vegetable sources. Vitamin D of animal source appears to be more potent for the human being than the vitamin D of vegetable source. The degree of superiority is not entirely established, but on the basis of evidence available it may be in the ratio of 1.5:1 when vitamin D milks are compared.

Animal source vitamin D milk with 135 rat units (U. S. P.) to the quart will prevent rickets, but this amount of vitamin D approaches closely the minimum effective level.

Prevention of rickets is not a criterion of adequacy of vitamin D intake. The amount of vitamin D that barely prevents rickets does not permit the best growth of infants, nor does it permit retentions of calcium and phosphorus as great as those considered desirable.

Animal source vitamin D in the amount present in one standard teaspoonful of average high grade cod liver oil or in milk containing 400 units to the quart is adequate for the infant from the standpoint of calcium retentions and growth. The minimal amount that is adequate is not known.

Vegetable source vitamin D has not been used in a manner which would determine directly the minimum rickets-preventive dose or the amount that permits good growth and retentions.

## REDUCING THE MORTALITY OF ACUTE APPENDICITIS

Vital statistics of the United States place the mortality rate for acute appendicitis at 9 for each hundred thousand of population for the year 1920 and at 15 per hundred thousand for the year 1932. The Metropolitan Life Insurance statistics indicate that the mortality rate of acute appendicitis rose from 10.6 per hundred thousand for the period from 1911 to 1914 inclusive to 14.1 for the period from 1927 to 1930 inclusive. Recent reports from various clinics, however, show a definite lowering in the operative mortality of acute appendicitis. The contradiction is explainable on the assumption of a higher incidence of the disease and a greater number of recognized and reported cases.

The factors contributing to the mortality of acute appendicitis include the age and sex of the patient, administration of cathartics before the operation, and delayed operation, as well as the skill and the judgment of the surgeon. Age is the most important single factor. The high mortality in the young is due to the greater virulence of the infection, to a tendency to early perforation, and to a faster spread of the pathologic alterations. Diagnostic difficulties resulting in delayed operation, and the more frequent recourse to cathartics combine to give a mortality rate of 20 per cent in children under the age of 3 years. The high mortality rate past middle life is due principally to diagnostic errors caused by the frequency of atypical forms, owing to a less vigorous reaction on the part of the organism. According to Wood,<sup>1</sup> atypical clinical manifestations in a group of patients past middle life were seen in 50 per cent, a correct preoperative diagnosis was made in only 62 per cent and the mortality rate was 28 per cent. Both the incidence and the mortality rate of acute appendicitis are lower for women than for men, probably because of greater resistance of the pelvic peritoneum in the former.

There is a general agreement supported by statistical studies<sup>2</sup> that the administration of cathartics seriously affects the situation.

The merits of the early operation are too well established to require reiteration. The technic of operation is simple and the mortality rate when operation is performed during the first twenty-four hours varies from a fraction of 1 per cent to 0. Recently it was suggested that the inversion of the stump of the amputated appendix is not necessary. Omission of this step will further simplify the operation of appendectomy. Appreciation of the fact that one must not expect to find all the five cardinal symptoms (pain, localized tenderness, muscle spasm, rise in temperature and leukocytosis) in every case and adherence to the principle of early operation will undoubtedly reduce this mortality still further.

As soon as perforation has taken place, the problem of care in appendicitis becomes tremendously complicated as to both the estimation of the existing pathologic changes and the question of operative intervention. According to Aschoff,<sup>3</sup> pathologic complications are present, on an average, thirty-five hours after the onset of the attack. The mortality in this group rapidly rises, to reach in cases complicated by diffuse peritonitis the appalling figures ranging with various authors from 15 to 60 per cent. The cases in which perforation has taken place may be divided into four groups: (1) walled off perforation, (2) encapsulated abscess, (3) acute limited peritonitis and (4) acute spreading more or less diffuse peritonitis. The greatest divergence of opinion exists with regard to the treatment of the late cases complicated by a spreading peritonitis. In contradistinction to the surgeon who advocates the removal of the focus of infection as the most important step in the treatment of every form of perforative peritonitis, except of course when the patient is moribund, there are those who believe that with the progression of the disease the good to be derived from the operation diminishes and the damage inflicted rises. The adherents of this opinion believe that surgical intervention in cases past forty-eight hours is without value. They insist that the infection is more likely to become delimited on the Ochsner plan of management and that intervention at this stage is bound to interfere with the plastic defensive and immunobiologic properties of the peritoneum. They propose that patients admitted to the hospital "too late for the early operation and too early for the late operation" be treated conservatively, preferably with the Ochsner management.

The objections raised against the dictum of no operation after the forty-eight hours are that (1) the history frequently cannot be relied on to establish the

3. Aschoff, Ludwig: Pathologie und Klinik in Einzeldarstellungen, Berlin, Julius Springer, 1930.

1. Wood, C. B.: Am. J. Surg. **26**:321 (Nov.) 1934.

number of hours, (2) the dictum forty-eight hours does not embrace all the factors comprising the picture, such as the extent of pathologic alterations, the virulence of the bacteria, the extent of intestinal paresis and the constitution of the patient, and (3) the adoption by the general practitioner of the dictum no operation after forty-eight hours is bound to do much harm. In favor of intervention it is argued that the continued discharge of infectious material and pathogenic organisms from the ruptured appendix and the intestine is bound to wear down the defensive power of the peritoneum and that therefore the removal of the focus of infection constitutes the most important step in the treatment of perforative peritonitis. Statistics are extant to prove the superiority of either method. Le Grand Guerry<sup>4</sup> reports a mortality rate of 1.4 per cent in a group of 135 cases of gangrenous ruptured appendicitis with diffuse peritonitis treated by the Ochsner method. On the other hand, Guy W. Horsley<sup>5</sup> reports a group of 502 consecutive cases of acute appendicitis in which an immediate operation was performed, with a mortality rate of 0.8 per cent. There can be no doubt that skill and judgment of the surgeon play an important part in the mortality rate of any operative procedure. The operative intervention in these complicated cases constitutes a major procedure. It is suggested that the high mortality rate of this group could be materially reduced if the chief surgeon, rather than the senior intern or the resident, would assume the responsibility for its management.

The controversy as to what to do with the patient who has a palpable swelling is less acute. Such a patient is admittedly not an emergency problem. The inflammatory swelling, in fact, represents a definite limitation of the pathologic condition. It is capable of a complete resolution without forming an abscess. An increase in the size of the swelling, pain, chills, rise in temperature and in leukocytes, and at times fluctuation establish the existence of an abscess. Watchful expectancy and intervention only when the abscess is not being absorbed is advocated by some. The more radical view is to operate regardless of the presence of a palpable swelling or the fact that it is regressing, the emphasis being placed on the removal of the appendix. An intermediate position is occupied by those who would operate in the presence of an inflammatory swelling or an early abscess, but who would wait for encapsulation in the case of a late abscess. They would further limit the procedure to an incision and drainage of the abscess without any attempt at the removal of the appendix. The objection to the policy of waiting is the possibility of a sudden rupture of the abscess leading to a most dangerous form of peritonitis.

The mortality rate of acute peritonitis complicating appendicitis has not been materially reduced by the

employment of various serums. The benefits of Havlicek's method of ultraviolet irradiation of the intestine in the course of operation for the purpose of releasing histamine-like substances capable of stimulating the portal circulation have not been confirmed by others.

Lowering of the mortality rate of acute appendicitis may follow education of the general practitioner to recognize the atypical forms, strict adherence to the principle of early operation, education of the public to abstain from the use of cathartics in the presence of abdominal pain, and responsibility for the neglected cases by the experienced surgeon rather than by the casual operator.

#### RELATION OF DIETARY CALCIUM AND PHOSPHORUS

The etiologic importance of improper diet in the production of rickets and the demands of the maternal organism for the formation of proper skeletal tissue of the young and for the subsequent lactation period have led to the accumulation of data demonstrating the significance of the ratio of calcium to phosphorus in the food. The normal ratio has been defined as from 2:1 to 1:2. Experimental studies of rickets in rats have demonstrated that diets with this relationship between the calcium and phosphorus will not permit rickets to develop and will cure the condition after it has been produced. The failure of normal deposition of calcium phosphate in the bone is usually attributed to the lack of normal concentration of either calcium or phosphorus (or both) in the blood serum and thus in the fluid bathing the bone. The rôle of calcium and phosphorus in determining reproductive success has been studied much less extensively, probably because the effects resulting from deficiencies of these elements appear only after several reproductive cycles.

The emphasis that has been placed on calcium and phosphorus ratios has in general resulted in a lack of consideration of the absolute amounts of either of these two elements in the diet. The low phosphorus type of rickets, which is believed to be most frequent clinically, is also the type most readily produced experimentally in rats under controlled conditions. Consequently, the distortion of the calcium to phosphorus ratio at the expense of the latter element has generally been employed in the experimental investigation of rickets. However, recent studies of both experimental rickets and the reproductive cycle have varied widely both in the ratios of calcium to phosphorus in the diet and in the absolute amounts of each of these two elements ingested. The interesting data obtained indicate a definite shift in emphasis from one of relative to one of absolute amounts of calcium and phosphorus ingested and serve to illustrate the inadequacy of dealing solely with ratios. Shohl and Wolbach<sup>1</sup> at the Harvard Med-

5. Horsley, G. W.: Improved Treatment of Appendicitis, *Virginia M. Month.* 62: 598 (Jan.) 1936.

1. Shohl, A. T., and Wolbach, S. B.: *J. Nutrition* 11: 275 (March 10) 1936.

ical School have extended and supplemented earlier investigations of the effects on bone formation in rats of high-calcium low-phosphorus diets to include low-calcium high-phosphorus diets. These investigators have correlated serum values and bone ash determinations with both ratios and levels of intake of these two elements; histologic pathology is also included, together with x-ray examination. This most recent work thus systematically completes a survey of the various calcium to phosphorus ratios and levels attainable with natural foodstuffs. In an equally complete investigation, Cox and Imboden<sup>2</sup> have studied the behavior of experimental rats receiving constant amounts of dietary calcium and phosphorus throughout the entire span of their reproductive life, thus obtaining an index of reproductive success.

The results of the Harvard work clearly indicate the fallacious interpretations that may result from a consideration solely of the calcium and phosphorus ratios of the diet. It seems evident that the absolute amounts of calcium and phosphorus is as important a factor in the production of rickets in rats as is the distortion of the accepted optimal dietary ratio for these two elements. It has been possible to produce rickets in experimental animals ingesting a diet low in both calcium and phosphorus, despite the fact that the calcium to phosphorus ratio in this type of diet was formerly considered "normal." The term "normal ratio," therefore, has thus largely lost its significance, for rickets may be produced with any ratio of calcium to phosphorus. As the absolute amounts of these mineral elements are increased, for any given ratio, the diet changes from a rachitogenic to a nonrachitogenic one. This importance of both level and ratio of these mineral elements is emphasized also by the studies of Cox and Imboden on the success of mother rats in producing and rearing young. A calcium to phosphorus ratio of 1.0, at a calcium level of 0.49 per cent, was established as the optimal level and ratio for successful gestation and lactation in this species. When the calcium level is not exactly known, it seems evident that a calcium phosphorus ratio of 1.0 for the mothers will approximate the optimal, as the highest ash contents of the 21 day old young were obtained with this ratio. At excessive mineral levels of 2.45 per cent, poor performance was obtained irrespective of the ratio. Phosphate in excess appeared to be better tolerated than an excess of calcium.

Although it is not always rational to transpose data obtained with one species to the explanation of normal and pathologic phenomena in another, the correlation of some of the data obtained in these two investigations with data in the literature for human beings is highly suggestive. Rickets in rats seems to bear a closer relation to rickets in infants and dogs than was formerly supposed, in that rickets is produced with diets in which

the ratio has been considered "normal," provided the amounts of calcium and phosphorus are sufficiently low. The essentials for the production of rickets thus appear to be an inadequacy of vitamin D accompanied by a relative deficiency of calcium or phosphorus or an absolute deficiency of either or both. The reproduction studies suggest that a calcium to phosphorus ratio of less than 1.0, which has been recommended by Sherman<sup>3</sup> for normal adult maintenance and by Toverud<sup>4</sup> for gestation, may be related to the low calcium intake which, in balance studies, has been observed in human pregnancy. It remains for future investigations to determine why a ratio of less than 1.0 is preferable at low calcium levels, but the importance of the absolute as well as the relative amount of dietary calcium and phosphorus appears to be clearly established by these recent studies.

### Current Comment

#### THE INTERNATIONAL COLLEGE OF SURGEONS—WHY?

Into the welter of scientific, pseudoscientific, medical and similar organizations which now appeal for the physician's patronage comes the International College of Surgeons, promoted by none other than H. Lyons Hunt, who has already to his credit [sic] the Association of Medical Editors and Authors. The prospectus indicates that the purpose of the organization is to bring together in closer harmony the leaders of the various colleges of surgeons now in existence; yet there is not the slightest evidence that the colleges of surgeons in any country have indicated their willingness to be brought together by this new organization. Among other objectives, the new "College" proposes to elevate the standards of surgery to a point at which international reciprocity may be realized; it is quite safe to say that international reciprocity in surgery must be a figment of the imagination for many generations to come. Apparently there will be a publicity department to keep the public informed as to what surgery can accomplish, prizes offered for research, a museum established in Geneva, a journal published and a building erected in Geneva, where the foreign promoter, A. Jentzer, resides. There are also to be annual meetings in the individual countries as well as a meeting every two years in Geneva. Finally, there will be three classes of members, notably members, fellows and masters, who will be entitled to place after their names the appropriate alphabetic insignia. The fellows are to be selected by election, appointment or examination. Apparently the first comers are all being appointed, but by whom and under what authority the prospectus sayeth not. Notwithstanding the obviously inflational character of this prospectus and the complete lack of any well authenticated background for this proposed organization, a considerable number of American physi-

4. Toverud, K. U.: *Nutritional Condition of New-Born Infants*, *Am. J. Dis. Child.* 46:954 (Nov., part 1) 1933.

2. Cox, W. M., Jr., and Imboden, Miriam: *J. Nutrition* 11:147 (Feb.) 1936.

cians have felt themselves highly honored by the receipt of the invitation and are already taking steps to extend the appendix to their names by the additional letters which they will purchase through this international college. There exists already an international surgical organization of standing and repute. No doubt an invitation to membership in this organization would be a considerable honor and well worthy of consideration by any competent surgeon. An invitation to membership in the present promotion might be considered more of an insult to the intelligence of the recipient than a recognition of extraordinary qualifications. One need not cast aspersions on the intelligence of the promoters. As psychologists they seem to have a fine insight into the weakness and folly of the average man, who likes to adorn himself in regalia and to adorn his cognomen with assorted alphabetic conglomerations.

#### INCREASE IN DUTY ON SURGICAL INSTRUMENTS FROM GERMANY

Beginning on or about July 11, importers of surgical instruments from Germany must, in addition to paying the normal tariff rate on the surgical instruments they import, deposit with the collector of customs an amount equal to 56 per cent of the invoice value of such instruments. This is to be held to cover the payment of an additional duty that it is proposed to levy, pending the ascertainment by the Treasury Department of the exact amount of the increase. The present normal rate of duty on surgical instruments is 55 per cent ad valorem, except in the case of instruments in chief value of glass, on which the rate is 70 per cent ad valorem. Section 303 of the Tariff Act of 1930 provides that whenever an exporting country pays, directly or indirectly, any bounty or grant to the exporter of any article manufactured or produced in that country and that article is dutiable under the act, then, on the importation of that article into the United States, an additional or countervailing duty shall be levied equal to the net amount of the bounty or grant given by the country from which it was exported. Germany, according to data in the files of the Treasury Department, grants certain bounties to exporters of surgical instruments, provisionally estimated by the Treasury Department as 56 per cent of the invoice value of the exported articles. This bounty enables German exporters of surgical instruments to compete in the markets of the United States to the disadvantage of our own domestic manufacturers of such instruments. Because of the bounties thus granted, according to a Treasury Decision approved by the Secretary of the Treasury June 4, 1936, the additional or countervailing duty is to be levied.

**The Average Basal Metabolism.**—In health, this basal energy metabolism averages about 70 calories per hour per man of average size, or about one calory per kilogram of body weight per hour. This is the minimum rate of expenditure of the normal man or woman when awake. During sleep the energy output is somewhat less, but when sitting erect it is more, while standing involves a still further expenditure of energy. A normal man, therefore, however sedentary he may be, is almost sure to expend in the course of the twenty-four hour day somewhat more than twenty-four times his basal hourly number of calories.—Sherman, H. C.: Food and Health, New York, Macmillan Company, 1934.

### CALIFORNIA

**Mussel Poisoning and Quarantine.**—All mussels from the ocean shore of California from the southern boundary of Ventura County north to the California-Oregon boundary, with the exception of San Francisco Bay, have been placed under quarantine for the period May 19 to September 30, according to the state department of health. This quarantine, established annually, was imposed earlier this year because of two fatal cases of mussel poisoning of residents of Los Angeles who gathered mussels and ate them in Ventura County. Never before have poisonous mussels been discovered so far south in California. Heretofore the quarantine area has extended from Monterey County to the Oregon state line. Since this order was issued it has become necessary to include the coastal area of Los Angeles County and investigations are being made as far south as the Mexican border in order to determine whether poisonous shellfish may be recovered in southern waters of California.

**Changes in Medical Faculty.**—Dr. LeRoy C. Abbott, clinical professor of orthopedic surgery, University of California Medical School, San Francisco, has been appointed professor of orthopedic surgery, effective July 1. Other changes in the faculty effective at that time include:

Dr. Theodore L. Althausen, to associate professor of medicine.  
Dr. Evelyn M. Anderson, assistant professor of medicine.  
Dr. Aberhardt C. Bost, assistant clinical professor of pediatrics.  
Dr. Frederic C. Bost, assistant clinical professor of orthopedic surgery.  
Dr. Mary E. Botsford, clinical professor of anesthesia, emeritus.  
Dr. Howard A. Brown, assistant clinical professor of surgery.  
Dr. Frederick S. Bruckman, assistant clinical professor of medicine.  
Dr. Jesse L. Carr, assistant professor of pathology.  
Dr. Joseph W. Crawford, assistant clinical professor of ophthalmology.  
Dr. William C. Deamer, assistant professor of pediatrics.  
Dr. Frederick C. Cordes, clinical professor of ophthalmology.  
Dr. William A. Key, assistant clinical professor of orthopedic surgery.  
Dr. Fred H. Kruse, clinical professor of medicine.  
Dr. Jesse L. Carr, assistant professor of medicine.  
Dr. Daniel G. Morton, assistant professor of obstetrics and gynecology.  
Dr. Edgar J. Munter, assistant clinical professor of medicine.  
Dr. Hartzell H. Ray, assistant clinical professor of pediatrics.  
Dr. William A. J. Reilly, assistant clinical professor of pediatrics.  
Dr. James F. Rinehart, associate professor of pathology.  
Dr. Harry C. Shepardson, associate clinical professor of medicine.  
Dr. Wallace B. Smith, clinical professor of otorhinolaryngology.

### COLORADO

**Personal.**—At a meeting of the Pueblo County Medical Society, April 7, life membership was conferred on Dr. Thomas A. Stoddard, Pueblo. Dr. Jesse W. White, Pueblo, addressed the society on "Thyroid and Pregnancy."—Dr. Vera H. Jones, Denver, has been named director of maternal and child health and care of crippled children under the state board of health and the social security administration, it is reported.—Dr. Claude E. Cooper is now professor of otolaryngology and head of the department at the University of Colorado School of Medicine, Denver.

**Society News.**—At a meeting of the Medical Society of the City and County of Denver, June 2, Dr. Robert K. Dixon spoke on "Treatment of Duodenal Ulcer" and Dr. William M. Bane, "Some External Eye Conditions."—At a meeting of the El Paso County Medical Society in Colorado Springs, May 6, speakers were, among others, Drs. Robert A. Youngman on "Pulmonary Hypertension"; Lyle B. Hart, "Cholelithic Disease with Postoperative Liver Shock," and Frederic F. DeMetovich, "Diverticulitis."—The Fremont County Medical Society was addressed in Canon City, May 25, by Drs. Albert W. Glatthar and Harold T. Low, both of Pueblo, on dermatology and tuberculosis of the epididymis and the prostate gland, respectively.

### CONNECTICUT

**Portrait of Dr. Dodge.**—Friends of Raymond Dodge, Ph.D., professor of psychology, Institute of Human Relations, Yale University, New Haven, have presented a portrait of him to the university. The portrait, by Lloyd Bowers Embury of the Yale School of Fine Arts, has been hung in the Institute of Human Relations. Dr. Dodge, who is 65 years old, has been affiliated with Yale since 1924; he has written extensively in his field. His retirement from the Yale faculty has been announced.

**Personal.**—Dr. George Mansfield Craig has been appointed medical examiner of Haddam.—Dr. Theodore G. Klumpp, assistant clinical professor of medicine in the department of internal medicine at Yale University School of Medicine, has been granted a leave of absence for the academic year 1936-1937 to go to Washington, where he will make a study of glandular and antianemic preparations with the Food and Drug Administration of the U. S. Department of Agriculture.—Dr. Robert V. Boyce has been named acting superintendent of health of Hartford, succeeding Dr. Thomas F. O'Brien, who was granted a leave of absence on account of illness.—Dr. Louis O. LaBella has been appointed health officer of Middletown.

**Society News.**—At the spring meeting of the Connecticut Association of Public Health and Clinical Laboratories, in Hartford, May 27, Dr. Alfred L. Burgdorf discussed "The Connecticut Marriage License Law," and Dr. Elliott S. Robinson, "Immunologic Application of Placental Extracts."—Dr. Walter I. Lillie, Philadelphia, discussed "Ophthalmological Changes Produced by Intracranial Lesions" before the Fairfield County Medical Association in Bridgeport, April 14, and Dr. Temple S. Fay, Philadelphia, "Diagnosis of Cerebral Tumors."—At a meeting of the Hartford County Medical Association in Hartford, April 7, Judge Newell Jennings of the superior court of Hartford County, among others, spoke on "Expert Medical Testimony."

### DISTRICT OF COLUMBIA

**Personal.**—Dr. Daniel L. Finucane has been appointed associate professor of clinical medicine at Georgetown University School of Medicine, Washington.

**The Borden Lectureship.**—The William Cline Borden Memorial Lectureship in Surgery has been established at George Washington University School of Medicine by Mrs. William Cline Borden and Dr. Daniel LeRay Borden, wife and son of the former dean of the medical school. The presentation for the Borden family was made at the May meeting of the university medical society by Dr. William Johnston Mallory, professor of medicine; it was accepted by Cloyd Heck Marvin, LL.D., president of the university. Dr. Borden's son, who is associate professor of surgery at George Washington, presented a biographic sketch of his father. It is planned to give the lectures at the medical school annually. Dr. Borden, who died in 1934, was professor of surgery and dean of George Washington University School of Medicine and surgeon in chief of the George Washington University Hospital from 1909 to June 1931.

**District Medical Election.**—Dr. William Mercer Sprigg, Washington, was elected president of the Medical Society of the District of Columbia, and Dr. Coursen B. Conklin was reelected secretary. The next annual session will be held at Washington, May 5-6, 1937. At the annual scientific assembly of the society, May 6-7, one feature was a "tri-state afternoon," when the following presented the program:

Dr. Upton D. Nc	Relation of the General Prac-
tionator to the	Centers.
Dr. William Way	Diagnosis and Treatment of
Tumors of the Intestinal Tract.	
Dr. James N. Greear Jr.,	Treatment of Eye Injuries.
Dr. Guy W. Leadbetter,	The Painful Shoulder.
Dr. Earle G. Breeding,	Causes and Treatment of Deafness.
Dr. Robert Lomax Wells,	Basic Clinical Factors in Evaluating Treat-
ment and Prognosis in Hyperthyroidism.	

Clinics were also presented and other speakers included:

Dr. Walter Clarke, New York, The New York Plan of Attack on Syphilis.  
Dr. James P. O'Hate, Boston, Practical Problems in Glomerulonephritis.  
Dr. Chevalier L. Jackson, Philadelphia, Gastroscoy as an Aid to Diagnosis.

### ILLINOIS

**Society News.**—Dr. Howard L. Alt, Chicago, addressed the Marion County Medical Society at Centralia, May 27, on "Use of Blood Chemistry in the Diagnosis and Treatment of Disease."—At a meeting of the Muskegon County Medical Society, May 22, Dr. Oscar B. Nugent, Chicago, spoke on "Diseases of the Eye in Relation to General Medicine."—Dr. Paul H. Holinger, Chicago, discussed bronchoscopy before the Kankakee County Medical Society, May 14.—At a joint meeting of the East St. Louis and Belleville branches of the St. Clair County Medical Society, June 4, Dr. Joseph Edgar Stewart, St. Louis, read a paper on fractures.—At a meeting of the Henry County Medical Society in Kewanee, May 14, Drs. Andrew C. Ivy and Raymond W. McNealey, Chicago, discussed "Therapy of Biliary Tract Disease from the Viewpoint of Applied Physiology" and "Surgical Manage-

ment of Biliary Tract Disease" respectively.—Dr. John R. Caulk, St. Louis, addressed the Macoupin County Medical Society in May on "Obstruction at the Bladder Neck in Men, Women and Children."—Dr. Aaron Arkin, Chicago, addressed the Peoria City Medical Society, May 26, on "Differential Diagnosis of Organic Heart Disease."—Dr. Frank H. Ewerhardt, St. Louis, discussed "Fever Therapy" before the Adams County Medical Society in Quincy, May 11.—The Vermilion County Medical Society was addressed, May 5, by Dr. James H. Hutton, Chicago, on treatment of hypertension and diabetes by x-rays.

### CHICAGO

**Eclampsics Wanted for Study.**—The Chicago Lying-In Hospital wishes several cases of eclampsia for study and for a motion picture. Physicians who have worthy indigent patients in this condition are asked to notify the hospital, Plaza 7200. The patients will be sent for and there will be no charge of any kind.

### KANSAS

**Society News.**—At a meeting of the Marion County Medical Society in Marion, May 6, Drs. Wendell M. Tate, Peabody, and Abraham C. Eitzen, Hillsboro, discussed "Leukemia with Its Nervous Manifestations" and "Epidemic Encephalitis" respectively.—The Greenwood County Medical Society was addressed in Eureka, May 6, by Dr. John L. Kleinheksel, Wichita, among others, on "Diabetes in Pregnancy" and "Diabetes as Associated with Hardening of the Arteries."—Dr. Daniel V. Conwell, Halstead, read a paper on "Organic Psychosis" before a recent meeting of the Northwest Kansas Medical Society in Norton, and Dr. Charles F. Taylor, Norton, gave an illustrated talk on a visit to the leper colony at Carville, La.—Dr. Lerton V. Dawson, Ottawa, discussed medical economics before the Osage County Medical Society in Alta Vista, May 29.—Dr. Ferdinand C. Helwig and Boyd S. Gardner, D.D.S., Kansas City, Mo., addressed a joint meeting of the Sumner County medical and dental societies in Wellington, May 28, on treatment of Vincent's angina by electrocoagulation.

### LOUISIANA

**Bills Introduced.**—S. 241 proposes to enact an entirely new workmen's compensation act. Among other things, it proposes to require an employer (1) to pay the compensation stated to an employee who has received "personal injury by accident arising out of and in the course of such employment" and (2) to "pay for reasonable medical, surgical and hospital services and medicines not to exceed \$250 in value, unless the employee refuses to allow them to be paid for by the employer." The italicized words seem particularly significant in view of the provision in the present workmen's compensation act which requires an employer "to furnish" reasonable medical, surgical and hospital services, and medicines in the amount noted above to injured workmen. This possibly leaves an inference that, if the present bill is adopted unaltered in this respect, an injured workman will have the right to select his own physician and thus render the employer liable within the limits noted above. S. 251 proposes to create a board of chiropractic examiners and to regulate the practice of chiropractic, defined as "the science of palpating and adjusting the articulations of the human spinal column by hand only." All persons of good moral character who have been continuously engaged in the practice of chiropractic in the state for twelve months prior to the passage of this bill are to be licensed without examination even though they have engaged in such practice in violation of the present law. All other applicants for licenses must be graduates of a school or college teaching chiropractic and giving a course of at least three years of six months each in anatomy, physiology, symptomatology, hygiene, sanitation, chiropractic analysis and principles and practice of chiropractic. H. 361 proposes to provide that physicians, midwives and other persons who are required to file certificates of births and deaths to the appropriate state or county officials shall be entitled to receive 25 cents for each certificate thus filed. H. 501 proposes to exempt licensed chiropractors from paying any state, city or parish license fees. H. 572, to amend the medical practice act, proposes to permit a person legally engaged in the business of refracting or fitting glasses to the human eye to use the title "optometrist." H. 659, to amend the dental practice act, proposes so to define unprofessional conduct, which is a ground for the revocation of a license to practice dentistry, as to embrace (1) all advertising other than the display of a professional card at the licentiate's place of business, (2) advertising through the press, on the radio or by the use of hand-

bills, circulars or periodicals other than professional cards stating only the name, address, profession, office hours and telephone connections of the licensee, and (3) employing or making use of advertising solicitors or publicity agents or soliciting employment personally or by representatives. H 681 proposes to create a "School Children's Health and Medical Board" to consist of three physicians, to be appointed by the governor for four year terms. The duties of the proposed board are to examine all school children of the state annually, to file a report of the findings of those examinations with the state board of education and to mail the parent or guardian of each child so examined a written report of the examination. The bill proposes to authorize an annual appropriation of \$200,000 to carry the proposed provisions of the bill into effect. S 45 proposes to prohibit a physician from disclosing in any legal proceedings, except at the instance of his patient, any communication made to him by a patient under his charge or by one seeking professional advice. H 347 proposes to enact a "state food, drugs and cosmetic act" and to repeal all laws in conflict therewith. The present laws proposed to be repealed conform closely to the present federal Pure Food and Drugs Act of 1906. The provisions of H 347, on the other hand correspond closely to the provisions of United States S 5, the Copeland bill, as it was reported out of committee in the United States House of Representatives, May 22, 1936, which was discussed and adversely criticized in THE JOURNAL, May 20, pages 1896-1898.

### MICHIGAN

**Program of Maternal and Child Health.**—A program of maternal and child health in Michigan, covering principally rural areas, was approved at a meeting of the house of delegates of the state medical society April 30. The plan, submitted by the state health department provides that before a program is set up in a county it must be approved by an advisory board appointed by the county medical society. Further, it will not include clinics, treatments or advice with reference to treatment of any kind, embracing only the cooperation of the private physician. Contemplated lectures to lay groups must first be presented in synopsis form to the advisory committee, while copies of the lecture must be given to each member of the society. Overactivity of lay groups as a result of this educational program will be discouraged and curtailed as far as possible according to the advice of the advisory committee of physicians, the state medical journal reports.

**Anniversary Microscope Presented to Dr. Novy.**—Dr. Frederick G. Novy, professor of bacteriology and chairman of the executive committee of the University of Michigan School of Medicine, Ann Arbor, was presented with a microscope at a luncheon for members of the American Association for the Advancement of Science in Rochester, N. Y., June 18. Edward Bausch, chairman of the board of directors of the Bausch and Lomb Company, made the presentation, and Dr. Novy gave an address entitled "Some Results of Microscopic Research Which Have Been of Significance for Human Welfare." This was the 250,000th microscope manufactured by Bausch and Lomb. The first instrument completed by this company was shown at the Philadelphia Centennial Exposition in 1876. This occasion also commemorates the fiftieth anniversary of Dr. Novy's graduation from the University of Michigan. Dr. Novy has been associated with Michigan since 1886. He became professor of bacteriology and director of the Hygienic Laboratory at the school in 1902, he has been chairman of the executive committee and faculty of the medical school since 1930 and is also dean.

### MINNESOTA

**Illegal Practitioners Sentenced.**—Ramon L. De Silvio was sentenced to one year at hard labor in the St. Louis County Work Farm by Judge Edward Freeman May 2 following his plea of guilty to practicing without a basic science certificate. He had recently been treating patients in Hibbing. De Silvio, a Negro, admitted he had falsely represented himself as a chemist and that he had never had any education above the sixth grade in school. He also admitted that he had been arrested for a similar offense in Boston. He had collected sums of money ranging from \$2.50 to \$17 per patient. Mrs. Frances Stanch, Albert Lea was sentenced to one year at hard labor in the woman's reformatory at Shakopee, April 21, by Judge Brill. She pleaded guilty to having performed an abortion stating that she had no medical education except such as she acquired as a practical nurse on a few occasions in Albert Lea.

### MISSISSIPPI

**Changes in Hospital Superintendents.**—Dr. John S. Hickman, Philadelphia, a member of the state legislature, has been appointed superintendent of the East Mississippi Hospital, Meridian, succeeding Dr. Russell R. Welch. The appointment was effective June 1. Dr. Louis M. Magee, Prentiss, has been named to succeed Dr. William K. Stowers as superintendent of the State Charity Hospital, Natchez. Dr. Thomas R. Beech, Ellisville, has been appointed superintendent of the South Mississippi Charity Hospital, Laurel, he succeeds Dr. Alcus J. Carter. Dr. Toney E. Hall, Shelby, has been designated superintendent of the State Charity Hospital at Jackson, succeeding Dr. DeWitt T. Brock. The appointment was effective June 1.

### MONTANA

**State Medical Meeting at Billings.**—The fifty-eighth annual meeting of the Medical Association of Montana will be held at the Commercial Club, Billings, July 8-9, under the presidency of Dr. Louis H. Fligman, Helena. Dr. James I. Wernham, Billings, president of the Yellowstone Valley Medical Society, will give the address of welcome, and Dr. Harry J. McGregor, Great Falls, vice president of the state association, the response. Speakers will include:

Dr. Roscoe C. Webb, Minneapolis, Fractures  
Dr. William A. O'Brien, Minneapolis, Treatment of Anemia, Indications for Radiation Therapy  
Dr. Anthony J. Lauzi, New York, Newer Methods of Diagnosis and Treatment of Pneumonia  
Dr. Ernest D. Hitchcock, Great Falls, Highlights in Routine Gastric Examinations  
Dr. Henry Schmitz, Chicago, Is There a Period of Absolute Sterility in Women? Report of Treatment of Pelvic Carcinomas with 800 Kilovolts After Thirty Months  
Dr. Lawrence M. Randall, Rochester, Indications for Cesarean Section  
Dr. Edward S. Murphy, Missoula, Montana's Pioneer Physician  
Dr. Arthur J. Movius, Billings, Subphrenic Abscess  
Dr. Allen R. Foss, Missoula, Manifestations of Allergy in General Practice

The Health Association of Montana will meet in the Commercial Club, July 6-7, and the Montana Academy of Ophthalmology, July 7, in the Northern Hotel.

### NEBRASKA

**Society News.**—Drs. Abram E. Bennett and Robert D. Schrock, Omaha, addressed the Madison Six Counties Medical Society at Norfolk, April 21, on "Artificial Fever Therapy: Results Obtained with the Kettering Hypertherm" and "Fractures at the Elbow and About the Knee Joint" respectively. Speakers at the spring meeting of the Third Councilor District Medical Society in Auburn, April 28, were the following members of the faculty of Creighton University College of Medicine, Omaha: Drs. Raymond L. Traynor, on "Treatment of Heart Failure", Ernest Kelly, "The Doctor and His Nervous Patients", Charles McMartin, "Diagnosis of Surgical Diseases of the Kidney", and Frederick J. Schwertly, "Infections of the Hands".

### NEW HAMPSHIRE

**State Medical Election.**—Dr. Frank E. Kittredge, Nashua, was elected president of the New Hampshire Medical Society at its meeting in Manchester, May 27. Dr. Samuel T. Ladd, Portsmouth, was elected vice president and Dr. Carleton R. Metcalf, Concord, reelected secretary. Next year's meeting will be held in Manchester.

### NEW YORK

**University News.**—Dr. Joseph C. Dorne, medical director of the Jewish Hospital, Philadelphia, will give a short course in hospital operation at Cornell University, Ithaca, in the two weeks beginning June 29. Admission is limited to those who are or have been actively engaged in hotel or hospital work. The Rockefeller Foundation has recently made two grants totaling \$16,400 to the University of Rochester School of Medicine and Dentistry. One of \$10,000 will be used for investigation of filtrable viruses under the direction of Dr. George Packer Berry, professor of bacteriology and associate professor of medicine, one of \$6,400 will be used to aid Dr. Stafford L. Warren, associate professor of medicine and radiology, in a study of the biologic effects of heat.

### New York City

**Personal.**—Dr. Frank Lusk Babbott Jr., president of Long Island College of Medicine, was one of six alumni of Columbia University who received the university medal for achievement since graduation. Dr. Babbott graduated from the College of Physicians and Surgeons in 1918.

**Society News.**—At a meeting of the International and Spanish-Speaking Association of Physicians, Dentists and Pharmacists, April 24, a symposium on arthritis was presented by Drs. Gertrude J. Chandlee, Jaques Kroner, Joseph Echtman and S. Epstein and Max Balaban, D.D.S. Dr. Jacob M. Gershberg was recently reelected president of this society; Dr. Reginald Burbank is general secretary and Dr. Emilio L. Hergert, recording secretary.—Dr. Charles R. Stockard addressed the New York Pathological Society, May 28, on "Hereditary Early Death in Localized Neurons with Resulting Paralysis in Dogs" and Drs. Eugene Clark and Adolph R. Berger, on "Hemorrhagic Extravasations into Valvular Leaflets and Their Relationship to Pulmonary Embolism."

**Symposium on Typhoid Carriers.**—An all day session of discussions of the typhoid carrier problem was held at New York Post Graduate Hospital, June 6, under the auspices of the combined medical and surgical clinic for the study of disease of the liver and biliary tract. Dr. Charles Gordon Heyd, Vice President of the American Medical Association, demonstrated cholecystectomy for cure of the carrier state and members of the faculty of New York Post Graduate Medical School spoke as follows: Drs. Eilif C. Hanssen, on "Treatment of Typhoid Carriers"; Ward J. MacNeal, "Bacteriology of Typhoid Infection"; John Russell Twiss and Bernard Marraffino, "Biliary Drainage in Detection and Release of Typhoid Carriers." In the afternoon the following program was presented:

Dr. Millard Knowlton, Hartford, Conn., The Typhoid Carrier Problem in Connecticut

Dr. Irvin E. Deibert, Camden, N. J., Results Following Cholecystectomy in Typhoid Carriers in the State of New Jersey.

Dr. Ernest L. Stebbins, Albany, N. Y., Detection and Control of Typhoid Carriers.

Dr. Samuel Frant, New York, The Typhoid Carrier Situation in New York City.

## NORTH CAROLINA

**Department for Crippled Children Established.**—The state department of health has recently established a department for crippled children in cooperation with the Children's Bureau of the U. S. Department of Labor, in the administration of the Social Security Act. Objectives outlined in the bulletin of the health department are to locate crippled children, of whom it is estimated there are about 20,000 in the state; to obtain expert diagnosis in all parts of the state; to provide expert treatment and hospital care; to establish a field supervisory service and follow-up service, and to engender public interest in the problem of the crippled child.

**Society News.**—The Catawba Valley Medical Society met in Morganton, May 26, with the following guest speakers, all of New York: Drs. John Russell Twiss, on "Differential Diagnosis and Clinical Management of Different Types of Gallbladder Disease"; Milton A. Bridges, "Dietary Management of Gallbladder Disease," and Rupert Franklin Carter, "Diagnosis and Management of Surgical Conditions with Respect to the Gallbladder." Dr. Isaac H. Manning, Chapel Hill, spoke on the Hospital Saving Association of North Carolina.—At the spring meeting of the Tenth District Medical Society at Spruce Pine, May 27, guest speakers included Drs. Olin B. Chamberlain, Charleston, S. C., on "Spastic Children" and Edward T. West, Johnson City, Tenn., "Appendicitis."

## NORTH DAKOTA

**Society News.**—Dr. Edgar A. Pray, Valley City, has been elected president of the North Dakota Anti-Tuberculosis Association.—Dr. Leonard W. Larson, Bismarck, was elected president of the North Dakota Health Officers' Association at its annual meeting in Jamestown May 18.—Dr. Archibald D. McCannel, Minot, addressed the Stutsman County Medical Society in April on modern economic aspects of medicine.—Dr. John P. Miller, Grand Forks, was elected president of the North Dakota Academy of Ophthalmology and Otolaryngology at the annual meeting in Jamestown, May 18, and Dr. Frederick L. Wicks, Valley City, was reelected secretary. Dr. Erling W. Hansen, Minneapolis, was the guest speaker on "Allergy in Ophthalmology."

## OHIO

**Public Health Association Meeting.**—Dr. Edgar R. Hiatt, Troy, was reelected president of the Ohio Public Health Association at the annual meeting in Columbus, May 14. Among speakers were Drs. Allen W. Freeman, Baltimore, on "Fundamentals in Public Health Organization Needed in Ohio"; George M. Curtis, Columbus, "Compression Therapy," and Louis I. Dublin, Ph.D., New York, "Analysis of the Tuberculosis Mortality Figures for the Past Thirty-Five Years."

**Society News.**—Drs. Charles I. Stephen, Ansonia, and Howard V. Dutrow, Dayton, addressed the Darke County Medical Society, Greenville, May 15, on "Hemophilia" and "Ethical, Political and Economic Changes in Medicine" respectively.—Dr. John W. McCammon, Cincinnati, addressed the Marion Academy of Medicine, May 5, on "Disabilities of the Feet."—Speakers at a meeting of the Putnam County Medical Society, Ottawa, May 6, were Drs. Frank C. Anderson, Mount Vernon, and Paul M. Holmes, Toledo, on "Diagnosis of Tuberculosis" and "Surgery in Tuberculosis" respectively.—At a meeting of the Columbiana County Medical Society, Lisbon, May 19, speakers included Drs. Jacob W. Schoolnic, East Liverpool, on "The Present Status of Treatment of Endocrine Disturbance"; Virgil E. McEldowney, Newell, W. Va., "Prevailing Therapy in Treatment of Hay Fever," and Lea A. Cobbs, Salem, "Significance of Arterial Hypertension."—At a meeting of the First District Medical Society in Wilmington, May 5, speakers were Drs. Malcolm O. Cook, Hamilton, on "Diagnosis and Treatment of Intestinal Obstructions"; Hugh C. Schick, Xenia, "Toxemias of Pregnancy"; Russell L. Haden, Cleveland, "Study and Treatment of Anemia," and Willis D. Gatch, Indianapolis, "Recognition and Treatment of Bowel Obstruction."—Dr. George B. Magrath, Boston, addressed the Montgomery County Medical Society, Dayton, at its annual dinner meeting, June 5, on his experiences as a medical examiner.

## OKLAHOMA

**Clinical Conference at Tulsa.**—The Tulsa Clinical Society presented its spring clinical conference June 10-11. Clinics were presented at Morningside and St. Johns Hospitals and there was a program of addresses at the Mayo Hotel Tuesday afternoon. Tuesday evening there was a banquet with Dr. Edward H. Cary, Dallas, Texas, as the guest speaker. Thursday afternoon was devoted to a golf tournament at the Avery Golf Club, followed by a barbecue dinner at the farm of Dr. Fred A. Glass at Owasso. Officers of the Tulsa Clinical Society are Drs. James C. Brogden, president; Russell C. Pigford, vice president, and Roger Q. Atchley, secretary.

## PENNSYLVANIA

**Society News.**—Dr. Franklin L. Payne, Philadelphia, addressed the Lycoming County Medical Society, Williamsport, June 12, on "Significance of Abnormal Bleeding at the Time of and After the Menopause." At an evening session Dr. Payne conducted a seminar and open discussion on menopausal abnormalities.—A symposium on hyperthyroidism was presented at a meeting of the Fayette County Medical Society, Uniontown, June 4, by Drs. Lucian D. Johnson, Connellsville, Elliott B. Edie, Clark M. Luman and Herbert Lund, all of Uniontown.—Dr. Paul P. Riggle, Washington, addressed the Washington County Medical Society, Washington, May 13, on "Etiology and Treatment of Peptic Ulcer."—Dr. James M. Blackwood addressed the Lawrence County Medical Society, New Castle, June 4, on "Tumors of the Eyeball."

## Philadelphia

**Personal.**—Dr. Leroy M. A. Maeder has resigned as medical director of the Pennsylvania Mental Hygiene Committee to devote his time to private practice.—Dr. William H. Teller was the guest of honor at a dinner, May 20, at the Warwick, celebrating fifty years of continuous service to the Jewish Hospital. The staff and association of ex-residents were hosts.

**University News.**—Dr. Isidor S. Ravdin, J. William White professor of surgical research in the University of Pennsylvania School of Medicine and professor of surgical research in the Graduate School of Medicine, has been appointed to the newly established George L. and Emily McMichael Harrison professorship of surgery at the university. The department of research surgery was established under the terms of the will of the late Mr. Harrison, who provided that the income of his residuary estate, approximating \$40,000 a year, be used for this purpose.

## TENNESSEE

**Health at Nashville.**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended June 6, indicate that the highest mortality rate (21.1) appeared for Nashville and the rate for the group of cities as a whole was 11.6. The rate for Nashville for the corresponding week of 1935 was 17.5 and that for the group of cities, 11.4. The annual rate for the eighty-six cities for the twenty-three weeks of 1936 was 13.2 as against a rate of 12.4 for the corresponding period of last year. Caution should be used in the interpretation of

these weekly figures, as they fluctuate widely. The fact that a city is a hospital center for a large area or that it has a large Negro population may tend to increase the death rate.

**Sectional Association Meetings**—The West Tennessee Medical and Surgical Association held its forty-fifth annual session in Jackson, May 21, under the presidency of Dr. James L. McMillan, Decaturville. Among speakers were Drs. Shields Abernathy, Memphis, on "Early Diagnosis and Prevention of Cancer"; Tinsley R. Harrison Nashville, "Cardiovascular Emergencies"; Willis C. Campbell, Memphis "Physiologic Principles Applied to the Treatment of Fractures," and Jere L. Crook, Jackson, "Personal Experiences in the Use of Radium for Relief of Cancer." Dr. Erle W. Hillsman, Trezevant, was elected president. The Upper Cumberland Medical Society held its annual meeting at Red Boiling Springs, June 16-17. Among guest speakers were Drs. William F. Gardner, Louisville, Ky., on "Advantageous Neurotic Reactions"; Carl C. Howard, Glasgow, Ky., "Conquest of Pain"; Franklin Jelsma, Louisville, "Diagnosis and Treatment of the More Common Brain Lesions," and Walter L. Rucks, Memphis, "Abdominal Pain in Children."

### TEXAS

**Health Education Campaign**—The state health department has announced a program of public health education to be financed with a grant from funds made available by the social security act. The first activity will be a campaign in connection with maternal and child health, carried out in cooperation with the state medical association. A two day refresher course for physicians will be presented in three towns in each councilor district of the association, under the direction of the councilor, assisted by a committee composed of an obstetrician, a pediatrician and a general practitioner. In addition a public health program will be presented on the evening of the two day meeting. The committee on maternal welfare of the state medical association has been asked to serve as an advisory committee to the state department of health. This committee has been enlarged to ten members and has changed its name to "committee on maternal and child health." Members are Drs. Calvin R. Hannah, Dallas, chairman, William W. Maxwell, San Antonio, George H. Beavers Jr. and Caleb O. Terrell, Fort Worth, Willard R. Cooke and William Boyd Reading, Galveston, Corwin L. Maxwell, Myra, Hugh Leshe Moore, Dallas, George W. Edgerton Jr., Harlingen, and Samuel E. Thompson, Kerrville.

### VIRGINIA

**University News**—Dr. Albert M. Snell, Rochester, Minn., addressed the University of Virginia Medical Society, May 7, on "Pathologic Physiology of Common Duct Stone." Dr. Frederick M. Hodges, Richmond, spoke April 27 on "X-Ray Therapy of Skin Infections."

### WASHINGTON

**Society News**—Dr. George Warren Pierce, San Francisco, addressed the King County Medical Society, Seattle, May 18, on "Problems of Reconstruction Surgery." At an extra meeting June 1 Dr. Laurence Selling, Portland, Ore., spoke on "Urologic Complications of Pernicious Anemia." The Seattle Surgical Society held a clinic meeting at Harborview Hall June 6, in honor of Dr. Albert I. Bouffleur. At a morning session there were clinics on fractures, the afternoon was devoted to traumatic surgery. At a dinner at the Rainier Club Dr. Homer D. Dudley and E. S. Franklin discussed medical and legal aspects respectively, of "Evaluation of Disability." Dr. William C. Spindel introduced Dr. Bouffleur, who related experiences of his long practice. Dr. Bouffleur, now 72 years old, was at one time assistant professor of surgery, Rush Medical College, Chicago.

### WISCONSIN

**Opening in Tuberculosis Work**—The state bureau of personnel announces an examination for a position as senior physician at the state tuberculosis sanatorium at Wales. The closing date for filing is July 3. Application blanks may be obtained from the bureau at the state capitol, Madison. The salary is \$200 a month less complete maintenance, subject to departmental waiver. Among the minimum qualifications for applicants are a license to practice in Wisconsin or eligibility for such a license, extensive experience in an institution, and familiarity with laws, rules and regulations relative to medical work in state institutions.

### GENERAL

**Medical Bill in Congress**—*Change in Status*. H. R. 12556 has been favorably reported to the Senate, without amendment, proposing to enact a Treasury Agency Organization Act. This bill proposes to create a Treasury Agency Service and to authorize the Secretary of the Treasury to coordinate the functions of investigation, detection or prevention of the violations of law conferred on the new Agency Service with the performance of the functions of investigation, detection or prevention of the violations of the narcotic laws conferred or imposed by law on the Bureau of Narcotics.

**Bequests and Donations**—The following bequests and donations have recently been announced:

Presbyterian Hospital, Philadelphia, \$35,000 from a trust estate left by Andrew Blair, who died in 1898.

Methodist Episcopal Hospital, Philadelphia, \$25,000 by the will of Miss Sarah Elizabeth Simpson.

Hahnemann Hospital, \$20,000, and Philadelphia Home for Incurables, \$10,000 in trust funds left by the late Marie W. Jeanes.

Salem City Hospital, Salem, Ohio, \$2,000 to endow two free rooms, from the will of Howard F. Stratton, Swarthmore, Pa.

Children's Hospital, Philadelphia, \$10,000 in trust from the estate of Howard Fuguet.

St. Luke's and Presbyterian hospitals, Chicago, \$25,000 each by the will of William O. Goodman.

University of Pennsylvania School of Medicine, Philadelphia, \$10,000 by the will of the late Dr. William M. Martin, Mobile, Ala., a graduate of 1874.

New York Hospital, New York, \$50,000 and Nassau Hospital, Mineola, L. I., \$25,000 by the will of Lewis Cass Ledyard Jr.

Rockefeller Institute and Lehigh Hospital, New York, \$10,000 each and Beth Israel Hospital, New York, \$6,000 by the will of the late Joseph Leblang.

Rush Hospital and Oncologic Hospital, Philadelphia, \$1,500 and \$1,000 respectively by the will of the late Marge S. Norton.

Lankenau Hospital, Philadelphia, \$5,000 by the will of Carl Grubman to endow a free bed.

New York University College of Medicine and New York Eye and Ear Infirmary, \$5,000 each by the will of the late Dr. Edward B. Deuch.

Brooklyn Jewish Hospital, \$1,000 by the will of the late Mrs. Rachel Levy.

**Society News**—Henry H. Donaldson, Ph.D., Philadelphia, was elected president of the American Neurological Association at the annual session in Atlantic City, June 3. Drs. Samuel D. Ingham, Los Angeles, and Edwin G. Zabriskie, New York, were elected vice presidents and Dr. Henry A. Riley, New York, was reelected secretary. Dr. Frederick J. Taussig, St. Louis, was elected president of the American Gynecological Society at its annual meeting in Atlantic City, May 26. Drs. George W. Kosmak, New York, and Sidney A. Chalfant, Pittsburgh, were elected vice presidents and Dr. Richard W. Telinde, Baltimore, secretary. Dr. Gilbert J. Thomas, Minneapolis, was elected president of the American Urological Association at its annual meeting in Boston, May 20. Dr. Clyde L. Deming, New Haven, Conn., was elected secretary. Dr. George M. Coates, Philadelphia, was elected president of the American Laryngological, Rhinological and Otological Society at its annual meeting in Denver, May 18-20. The following vice presidents were elected: Drs. De Forest C. Jarvis, Barre, Vt.; Charles D. Blassingame, Memphis, Tenn.; Alfred Levy, Chicago; Frederick A. Figi, Rochester, Minn.; and David R. Higbee, San Diego. Dr. Carlton Stewart Nash, Rochester, N. Y., was elected secretary.

## Government Services

### Examination for Public Health Service

The U. S. Public Health Service announces that an examination for entrance into the service will be held in Washington, D. C., June 29. Immediate application should be made to the surgeon general by those who wish to take the examination. Applicants must be graduates of class A medical colleges and not more than 39 years old at the time of the examination. Following are the minimum requirements: three years of college premedical work, four years of medical education with a medical degree, two years of graduate instruction or work in research and two additional years devoted to the subject in which graduate instruction was received or to research. The entrance salary is \$3,339 for appointees without dependents, \$3,798 for those with dependents. The examination will consist of a thorough physical examination and academic, professional and general fitness tests, all of which consumes approximately about one week. Candidates must defray their own traveling expenses to Washington.

### LONDON

(From Our Regular Correspondent)

May 2, 1936.

#### The Medical Aspects of Abortion

The law concerning abortion is unsatisfactory. It lays down penalties for "unlawfully" inducing abortion without stating what is lawful induction. Hence physicians are often unwilling to perform therapeutic abortion owing to uncertainty as to the legal risk. Therefore in 1934 the council of the British Medical Association appointed a committee consisting of obstetricians and others to report on the medical aspects of abortion. This committee has now made a lengthy report. It has been suggested that the physician need have no uncertainty as to his freedom to induce abortion, as the law is adaptable in practice, although not in theory, to changes in social thought. But the committee replies that the responsibility of interpreting public opinion on such matters should not be placed on the physician. Further, physicians differ widely in their views and in their practice. As an example, pregnancy following rape below the age of consent may be taken. The law seems to imply that pregnancy in a girl of 13, whose pelvis is too small for safe delivery, should be carried to term for cesarean section. What is the wish of the community? Some physicians would refuse to induce abortion, while others would not hesitate. A similar difference exists as to abortion for eugenic reasons. Leading physicians submitted memoranda to the committee. It is generally believed that termination of pregnancy in the early months is legal when carried out with the object of safeguarding the mother's life or health. Nevertheless the law leaves the physician exposed to risks. It is not only conviction which is dreaded; indictment, however unjustifiable, may damage his reputation. The result is that he may demur to perform therapeutic abortion, with risk of sacrifice of the health or life of the patient. While it is impossible to provide exact indications for the induction of abortion, the committee considers that the law should at least contain an explicit statement of the principles of the lawful termination of pregnancy. But this would not remove all difficulties, for differences of opinion with regard to the urgency of the medical indications may expose an honorable physician to the risk of his judgment being publicly impugned, even when he is protected against the major risk of criminal intent. To safeguard him the committee suggests that abortion should be carried out only on the approval of two physicians. To remove any question of collusion, one might have some recognized status in the matter.

#### THE INDICATIONS FOR THERAPEUTIC ABORTION

The committee summarizes at length the indications for therapeutic abortion. In heart disease a previous attack of congestive heart failure is a certain indication. Congestive heart failure during the first three months is not common, but when it occurs so early the uterus should be emptied after suitable preoperative treatment. Other indications are auricular fibrillation, repeated hemoptyses, paroxysmal tachycardia, mitral stenosis with evidence of antecedent embolism, myocardial degeneration, arterial disease with high blood pressure, enlarged heart and progressive bacterial endocarditis.

Of renal conditions, chronic nephritis is an indication not only because of the damaging effect of pregnancy on the kidneys but also because of the liability of the death of the fetus. A history of eclampsia or preeclampsia in a previous pregnancy with recurrence of symptoms at an early stage of a subsequent pregnancy may necessitate induction. So may severe pyelitis or tuberculosis.

Of pulmonary conditions, tuberculosis is largely the problem. In active tuberculosis the question should be considered in the early months. After the third or the early part of the fourth month the effects of the disease are as marked after intervention as if the pregnancy had been allowed to proceed. In acute rapidly spreading disease, even in the early months, induction as a rule is of little use. But when there is a history of antecedent active disease and indications of recent activity are found, and especially if there is evidence of laryngeal or intestinal lesions, abortion is indicated in the early months. In arrested tuberculosis the pregnancy should be allowed to continue.

Blood conditions—leukemia, Hodgkin's disease, splenic or aplastic anemia, refractory pernicious anemia and thrombocytopenia—may be indications. Eugenic considerations are generally regarded as outside the scope of therapeutic abortion, but the committee believes that there may be justifiable indications. The offspring of two mental defectives will almost certainly be mentally defective. Therapeutic abortion should then be considered. Other cases in which it might be thought allowable are (1) if the father and one child are mental defectives, (2) if the father is psychopathic and one child a mental defective, and (3) if two mentally defective children have already been born.

#### Investigation of Causes of Road Accidents

The Ministry of Transport has begun a new investigation of the circumstances and causes of road accidents. Particulars of every accident, whether fatal or not, are being noted by the police and will be forwarded to the ministry for examination and analysis. This inquiry will reveal for the first time how many of the 200,000 persons injured yearly on the roads of Great Britain are only slightly hurt and how many escaped death at the cost of maiming or serious injuries. In deciding on a wider inquiry the ministry was influenced by the fact that the 6,000 to 7,000 fatal cases investigated since the beginning of last year form about 3 per cent of the total accidents involving personal injury. When reporting accidents the police will in future record the general character of the road (whether residential, shopping or business), the presence or absence of street car tracks, the width of the roadway, the weather and light, and features such as road junctions, subways or marked pedestrian crossings within a specified distance of the accident. Notes will be made of the age and sex of the persons involved and of their movements and those of the vehicles concerned immediately before the accident. The inquiry will show for the first time how many accidents occur where a speed limit is in operation and where there is no speed limit. In every case the police will be asked to state the main and contributory causes of the accidents, and these have been codified under sixty-four heads. These facts will be entered on a printed form.

#### SAFER ROADS FOR CHILDREN

Already forty-three children under 15 have been killed in London this year. A committee appointed by the board of education and the ministry of transport to advise on the promotion of safety among school children has made a most searching inquiry into the causes of road accidents among children. In their report they state that at the outset they were impressed by the serious character of the problem, its rapid growth in recent years and the complexity of the causes. Nothing less than sustained national effort, toward which every road user should contribute, will suffice to overcome this appalling menace to child life. In 1920, 857 children under 15 were killed in road accidents. By 1930 the figure had risen to 1,433. Since then the numbers have slightly declined, but in 1933 the total was 1,245. In London the fatal accident rate in 1921 was 9 per hundred thousand of the child population. In 1933 this had risen to 13. For the same two years the rates for nonfatal

accidents were 297 and 617. Analysis of the fatal accident rate for London shows that it rises rapidly from the age of 2 and is highest between the ages of 4 and 8. After this there is a decline, but after 12 there is an increase caused by fatalities among child cyclists. At all age periods more boys than girls are killed, probably because they are more venturesome. Among the causes of accidents to children are playing in the carriage way, impulsiveness, inexperience, the stealing of rides on cars, and cycling. Allowing children to ride bicycles too large for them or not in roadworthy condition increases the risk. One source of accident is the riding of scooters.

The committee makes fifty-one recommendations. These include far more drastic regulations concerning road traffic. County councils should set up children's safety committees to make periodic surveys of their areas from the point of view of road safety, including protection at road crossings near schools. Children under 7 should not be allowed on the highway unaccompanied. The most effective safeguard at busy road crossings near schools is a police constable, but authorized adult patrols might be tried. A conspicuous school sign which gives warning when children are entering or leaving school is advocated. More playing fields should be provided to keep the children off the streets. Where traffic conditions are dangerous, children should be prohibited from cycling to school. Young children should be instructed in elementary matters of road safety. The minister of transport has already authorized a special portable road sign for persons assisting children to cross the road. In large red letters on a white ground is "Stop" followed by "Children Crossing."

#### The New Midwifery Service

In the house of commons Sir Kenneth Wood, minister of health, moved the second reading of the midwives bill, the purpose of which is to establish a service of salaried trained midwives, so that every expectant mother, whatever her circumstances, can obtain a qualified midwife. The bill is also designed to raise the status of the midwifery profession by providing adequate salaries and facilities for further instruction. In the last ten years nearly 2,000 mothers have died annually in childbirth. The failure of maternal mortality to yield hardly a decimal point to sustained attacks has been a matter of national concern, contrasting with the notable results in the case of infant mortality. Last year the government spent over \$15,000,000 on maternity and child welfare, yet the maternal mortality was not substantially reduced.

The local authorities will control the new service. They will fix the salaries of the midwives employed by them and the fees to be charged. A midwife now practicing can either apply for a salaried post or continue her independent practice. On the other hand, she can within three years of the coming into operation of the new scheme surrender her practicing certificate and receive as compensation thrice the average of her emoluments for the preceding three years. The local authority can call on old or infirm midwives, unable to perform their duties satisfactorily, to retire, in which case they will receive five times the net value of their practice in the preceding three years. Arrangements are provided to enable midwives to keep abreast of current practice by attending refresher courses. The government will assist the local authorities by supplying approximately half the total additional cost incurred for the service. But the government grant will vary with the needs of the area from 25 or 30 per cent in the richest areas to 80 per cent in the poorest.

The local authorities will also be encouraged to develop further their antepartum clinics, which have increased by 20 per cent since 1931. The case of London has been specially considered, as salaried midwives are already provided by the London voluntary hospitals and about 25 per cent of the labors take place in municipal hospitals, where there are antepartum

clinics and specialists in all branches of maternity work. The new salaried midwives will have these services at their back and can enlarge their experience by taking duty in the hospitals when not engaged in domiciliary work.

#### Infant Vaccinated with BCG Infected by Tuberculous Parent

At a meeting, March 27, Weill-Hallé and Mouchotte reported a case showing that BCG vaccination of the new-born against tuberculosis can be rendered ineffective if the infant remains in contact with parents having pulmonary tuberculosis. The infant was brought to the crèche at the age of 10 months on account of a tuberculous osteomyelitis of one of the phalanges of the left index finger and a tuberculous submental lymph node. On the fifth, seventh and ninth days after birth, the BCG vaccine had been given by mouth. Pasteurized cow's milk had served as nourishment, and until an attack of pertussis at the age of 7 months the infant had appeared to be in good health. No tubercle bacilli were found in the pus from the suppurating submental lymph node, but three guinea-pigs inoculated at the Pasteur Institute with the same pus all presented marked tuberculous changes at necropsy. The type of tubercle bacillus found in the animal lesions has not yet been determined. There was also a positive skin reaction to tuberculin at the time the infant was first seen by the authors. The father of the infant had been married twice, his first wife dying of pulmonary tuberculosis. The second marriage took place two years later. The mother of the infant was in good health at the time the baby was born, so far as roentgenologic, clinical and bacteriologic examinations were concerned. The father also appeared to be in good health and several examinations including those of the sputum were said to be negative. But, on being subjected to another examination by Weill-Hallé and Mouchotte, although there was no clinical evidence of tuberculosis, roentgenography revealed the presence of a cavity in the right upper lobe, and a large number of tubercle bacilli were found in the sputum. The infant had evidently been temporarily immunized by the BCG vaccine and then infected through inhalation of the dried sputum of the father.

If such a careful examination of the infant's parents had not been made, the BCG vaccine would have been unjustly accused as having given rise to the tuberculosis found in the infant. The authors emphasized the necessity of controlling the vaccination of infants and that of revaccination.

#### Infant Vaccinated with BCG Infected by Apparently Cured Mother

As a continuation of the discussion of the immunizing value of the BCG vaccine given by mouth to the new-born, Blechmann and Mély reported a case at the April 3 meeting of the Société médicale des hôpitaux of Paris. Two similar cases had been reported by the authors, one in 1930 and a second in 1935. In this third case an infant who had been given the BCG vaccine at birth died at the age of 4½ months of a tuberculous meningitis. Lumbar puncture had revealed a marked lymphocytosis and the presence of tubercle bacilli, verified by Nègre at the Pasteur Institute as being of the human type. The tuberculin skin reaction on the fourth day after the onset of the meningitis symptoms had been markedly positive.

The infant, after having been given the BCG vaccine by mouth immediately after birth, was isolated for the first six weeks but then allowed to be taken care of by the mother. The latter, it was learned on inquiry, had presented signs of a pulmonary tuberculosis about two years before her marriage and had been treated since that time by repeated artificial pneumothorax insufflations. Believing herself cured, the mother

thought that there was no longer any danger of infecting her infant. Blechmann and Mély emphasize the fact that an artificial pneumothorax for pulmonary tuberculosis does not eliminate the possibility of infecting those who live in close proximity of such a patient.

Paraf stated that absorption of the BCG vaccine, administered by mouth, does not always take place. For this reason some vaccinated nurslings are not immunized at all and others do not absorb more than a few bacilli, a quantity insufficient to give rise to the lesions which should serve as a "premunition" against later tuberculous infection. After subcutaneous and, even more so, after oral administration, the BCG vaccine gives only a relative immunity, which is adequate against mild or moderately active infections but is not constant in its ability to combat a severe contamination by a tuberculous father or mother.

It is difficult to state that an individual is no longer a source of infection, after treatment by artificial pneumothorax, even though from a clinical and radiologic standpoint, the patient appears cured. Paraf had often found that the sputum of such patients still contained tubercle bacilli, so that prolonged isolation is indicated. For this reason, in a monograph entitled "Immunity Against Tuberculosis" the author has raised the question as to whether it is worth while to attempt to vaccinate the new-born with the BCG if exposure to severe infection at home is unavoidable. It would appear to be better to vaccinate only older children and adolescents, not yet allergic, thus conferring an immunity which would enable them to resist the less severe infections to which they might be exposed.

Marfan, continuing the discussion, said that as a rule the skin reactions observed in nurslings given the BCG vaccine were either slight or negative; hence the marked reaction in Blechmann and Mély's case showed that the tuberculous infection was of a highly virulent type. The infant should have been kept away from the mother longer than six weeks. The "premunition" or establishment of immunity after administration of the BCG vaccine requires often several months. Vaccinated nurslings should be isolated for a long period from any contact with tuberculous individuals, especially from a parent who has an artificial pneumothorax.

Lesne endorsed Marfan's views and said that nurslings given the BCG vaccine should be kept away from surroundings in which contamination is possible until they are at least 7 months old; otherwise a sense of false security is entertained by the parents.

Lelong stated that at present no test existed which enabled one to state that an infant is immune. The cutaneous reaction and intradermoreaction indicate the presence of infection and not immunity.

#### **Tuberculous (Bovine Type) Meningitis in Infant Vaccinated with BCG**

The question as to whether the oral administration of the BCG vaccine is able to immunize nurslings against tuberculosis has been actively and at times acrimoniously debated here during the last two years. Mention has been made of the appointment of a committee by the Pasteur Institute of Paris to hear arguments from both sides. The report of this committee has not yet been published. At the March 27 meeting of the Société médicale des hôpitaux of Paris, two pediatricians of Strasbourg, Rohmer and Vallette, reported the case of an infant born May 16, 1934, which was given the BCG vaccine by mouth without any apparent ill effects. The child had never been nursed by the mother. A revaccination was carried out at the age of 13 months, the infant appearing at that time in excellent condition. During the following two months, symptoms of a mild intestinal nature appeared, accompanied on one occasion by emesis. A short period of slight

elevation of temperature was observed about the end of August, and three weeks later the infant appeared to be somnolent, vomited occasionally and suffered from constipation. Examination, September 18, revealed neck rigidity, a positive Kernig sign and apathy. Stains of the fluid obtained by lumbar puncture showed the presence of tubercle bacilli. Guinea-pig inoculation with the cerebrospinal fluid resulted in the discovery of a generalized tuberculosis. The child died September 21, and the necropsy revealed a caseous tuberculosis of the ileum, enlarged mesenteric lymph nodes, a few tubercles in the liver and spleen, and a tuberculous meningo-encephalitis. Pus from the mesenteric nodes was found to contain tubercle bacilli. Some of the pus was inoculated into guinea-pigs. When the latter were killed, lymph nodes containing pus were encountered. This pus studied simultaneously at the bacteriologic laboratory of the University of Strasbourg and at the Pasteur Institute of Paris showed, on inoculation into rabbits, a pure culture of the bovine type of tubercle bacilli. Evidently the atrium of infection in the infant was in the intestine.

The question arises as to the date of the primary infection. The authors quote Wallgren as showing that a tuberculous meningitis, as a general rule, occurs from two to four months after the primary infection; hence Rohmer and Vallette believe that such a primary infection occurred at the time of revaccination (June 15), the symptoms of the meningitis appearing about two months later. Both parents had a history of old, apparently healed tuberculous infection but none of recent character, so this source could be excluded, especially in view of the bovine type of bacilli having been found in the pus of the mesenteric lymph nodes of the infant. Examination of both parents recently also failed to show any tuberculous foci. A source of infection, so far as food was concerned, could also be excluded, according to Rohmer and Vallette. A puzzling feature was the fact that, as verified by Professor Guérin of the Pasteur Institute, Paris, 449 infants had been vaccinated or revaccinated with the same vaccine and that four guinea-pigs inoculated with the vaccine were in perfect condition 213 days later. In the discussion, Guérin said that infants were more frequently infected with tubercle bacilli of the bovine type than is commonly thought, the incidence being at least 10 per cent in France and much higher in the United States and Scandinavian countries, wherefore the instruction to parents never to give an infant unsterilized cow's milk. Guérin believed that the possibility of an infection (with the bovine type) of the parents of this child could not be discarded. The BCG vaccine is of bovine origin, of a strain which originally was very virulent, but during a period of thirteen years, by successive cultures repeated every fifteen days, a stable innocuous strain had been obtained. Even though the milk had been sterilized by the parents of the infant (in Rohmer's case) one could not exclude as a source of infection the cream and butter ingested by the infant.

Weill-Hallé stated that he had employed the same vaccine as was used in Rohmer's case, without observing any accidents.

Tixier questioned the efficacy of the BCG vaccine.

Lesne and Saenz found the bovine type in the cerebrospinal fluid of only seven of 115 cases of tuberculous meningitis.

Marfan believed it unwise to condemn the BCG vaccine from an isolated case such as that reported by Rohmer. The infant had evidently not been immunized, possibly because of nonabsorption of the vaccine. A positive skin reaction in vaccinated infants enables one to determine whether or not the vaccination has been successful.

#### **Two Cases of Bacillus of Pfeiffer Septicemia**

Lemierre, Meyer and Laplane reported two cases of septicemia caused by the bacillus of Pfeiffer, March 13, before the Société médicale des hôpitaux of Paris. Blood cultures yielding the bacillus of Pfeiffer have thus far been reported only

during the course of an influenza epidemic accompanied by severe lung complications or in certain bronchopneumonias, measles or pertussis. Lemierre and his associates reported the case of a woman, aged 22, who was taken ill with symptoms of a severe pharyngitis in August 1935, accompanied by high temperatures, chills, fetid breath and the presence of false membranes of a gangrenous aspect. Following an apparent recovery the chills and fever recurred about three months later, with marked joint symptoms. In the middle of October, signs of pulmonary involvement appeared. When first seen by Lemierre at about this period, the patient presented all the general symptoms of a severe septicemia, with some evidences of localization in the right lung and a systolic murmur. Blood cultures at the end of October were positive for the bacillus of Pfeiffer. The patient died about two weeks later but necropsy could not be obtained. The atrium for the endocarditis and generalized infection had evidently been the pharynx. The appearance of the symptoms of septicemia, eleven days after apparent recovery from the pharyngitis, is not an unusual observation. The interesting feature is the absence of the signs of influenzal character at the onset.

The second case was that of a woman, aged 44, who had a severe tonsillitis with sudden symptoms of edema of the glottis, Oct. 22, 1934. Three blood cultures on the third, sixth and eleventh days after admission to Professor Lemierre's service were all positive for the bacillus of Pfeiffer. The pharyngeal symptoms were accompanied by relatively high fever, evidence of multiple joint localization, signs of bilateral pulmonary congestion, anemia, restlessness and emaciation.

Two later blood cultures were negative despite the persistence of the fever. In the second case the atrium had also been in the pharynx but the clinical evidences of a generalized infection appeared almost immediately. An interesting feature of the onset was the presence of such marked edema of the pharynx and larynx that one could suspect, on examination of these structures, an infection due to the bacillus of Pfeiffer. Two similar recent observations were found in the literature, in which the onset of symptoms was marked by the presence of an intense laryngeal dyspnea, so that a diphtheria was at first suspected.

### The Biologic Effect of Alcohol on Metabolism

The Berlin physiologist Bickel investigated the influence of blood sugar content on the course of the alimentary-alcoholic curve. Experiments performed on rabbits having normal metabolism demonstrated a dependence of the alcohol content of the blood on the sugar content, since a rich sugar content seems to protect the alcohol from oxidation. The alcohol curve consequently sinks more slowly after ingestion of alcohol and sugar than if alcohol alone has been supplied. From comparative experimentation with insulin it was determined that in subjects with normal blood sugar content the sugar and alcohol curve declined more rapidly subsequent to ingestion of alcohol, and simultaneously a decrease in the blood alcohol took place. If, however, in the same insulin experiment, a substantial quantity of sugar was supplied, the decrease in the alcohol content was no longer evident. The further significant observation was made that the intoxication of the subjects was abbreviated by administration of insulin but was substantially increased if a high blood sugar content was present at the same time. On the other hand, defective utilization of alcohol by diabetic subjects is traceable to the insulin deficiency. In explaining how the insulin effects an abbreviation of the toxic state, Bickel declares it demonstrable that a virtual "blockade produced by

insulin" among the ganglion cells opposes the ingested alcohol. The high sugar content appears to retard the entrance of further amounts of alcohol into the tissues.

Of forensic importance is the finding that no quantitative relationship exists between the high level of blood alcohol content and the low level of the intoxication. Individual sensitivity to alcohol must be viewed in the same manner as sensitivities to other agents (tobacco or coffee for example). The value of blood alcohol determined subsequent to an automobile accident, for example, is not alone to be regarded as a satisfactory criterion of drunkenness.

During the discussion of this topic by the Berlin Medical Society, Dr. Wagner, the medical examiner, declared that the utmost caution should govern the interpretation of the blood alcohol content in accident cases. Only values in excess of 2 per thousand can be construed as certain indications of genuine intoxication. Occasionally the curve of alcoholic content in the tolerance test may be an additional important aid. Professor Heubner, pharmacologist, stressed the importance of the type of alcoholic beverage ingested, since the toxic effect may be modified by diverse additional ingredients.

### Physical Examinations for Army Service

Universal compulsory military service became reinstated by law in the German reich, March 16, 1935. This necessitated hasty preparations for the examination of the army class immediately scheduled for service and the establishment of a statistical working basis that would facilitate the examination of future classes. The plan, as pointed out by Dr. Müller of the war ministry, was to examine for immediate military service (wehrdienst) all men born in 1914 and to examine all men born in 1915 for the work service (arbeitsdienst), which precedes regular military duty. In addition, 100,000 volunteers were to be inspected. Records of similar service examinations in prewar times, the last of which took place in 1913, provide a certain basis for comparison. The physicians conducting the 1935 examinations, "impressed by the eagerness of the youth to enlist," appear in several instances to have been more lenient in their decisions than the examiners of prewar days.

The principal observations of the 1935 examinations are given in table I.

Comparison of the 1935 figures with the figures for 1913 gives the results shown in table 2.

Thus, according to these statistics, 83 per cent of those examined were declared fit for active service in 1935 against 76 per cent in 1913. The figures, however, must not be taken to

TABLE 1.—Results of Examinations for War Service in 1935

	Percentage of Conscripts	Percentage of Volunteers	Percentage of Both Groups
Fit for service.....	75.91	86.77	77.02
Fit on condition.....	6.23	4.21	6.03
Total .....	82.14	90.98	83.05
Unfit for service:			
Temporarily unfit .....	6.18	3.65	5.92
Fit for limited service..	8.47	4.72	8.08
Unfit for military service (wehrdienst) .....	2.04	0.53	1.89
Completely unfit .....	1.17	0.07	1.06
Totals .....	17.86	8.97	16.95

represent any such actual difference in the physical condition of recruits, since the present method of classification differs from the method in use before the war. The examination of recruits in large numbers always provides an excellent opportunity to gain an insight into the physical condition of the nation as a whole. With this in mind the examiners of 1935 took into account in addition to those physical and mental

defects which are deemed important from a military point of view all noteworthy defects and infirmities that could be established by examination. The following figures for 1935 show the percentages of those examined presenting various categories of disease: general debility 7.02, circulatory diseases 7.58, defects of the limbs 19.02, diseases of the ear 3.76, defective ocular refraction 11.31, varices and sequels 5.98, partial or complete flatfoot 23.91, nervous diseases 2.43, crippled and deformed conditions of the vertebral column 16.97, bad teeth 14.86, additional diseases of the eye including blindness 3.05, respiratory diseases 1.51, abdominal hernias 4.86, skin diseases and cicatrices 12.25, chronic bone disease 2.19, chronic digestive disorders 4.77, diseases of the genito-urinary organs 1.57, goiter 4.99, stuttering and mutism 0.75, diseases of the nose, tongue

TABLE 2—Comparison of 1935 Figures with Those of 1913

	1913 Percentage	1935 Percentage
Fit	63.6	77.07
Fit on condition	12.4	6.03
Fit for limited service	18.9	8.08
Unfit for military service (wehrdienst)	5.0	1.89
Completely unfit		1.06
Temporarily unfit		5.92

and palate 3.59, general diseases (rheumatism and gout, for example) 0.89, obesity 0.12.

It will be seen that pedal defects occupy first place. The number of men with defective ocular refraction also appears excessively high.

#### Prof. Joseph Jadassohn Dead

The dermatologist Prof. Joseph Jadassohn died March 25 in his seventy-third year at Zurich, where he had been living in retirement. A pupil of the dermatologist Neisser, Jadassohn at an early age was appointed director of the University dermatologic clinic at Bern, Switzerland. While occupying this post he led the exceedingly active life of a successful scientist and practitioner. He remained at Bern from 1896 to 1917 and then came to Breslau in his home province as ordinarius. Thereafter, although enticing offers beckoned to him from other regions, he remained loyal to his Silesia. In 1931 he retired. The foregoing are but a few of the important dates in the chronology of a busy and fruitful life. Few representatives of his field of specialization have exercised a direct influence on the development of the dermatologic anschauung comparable to that of Jadassohn. With great modesty he toiled constantly for what seemed to him the important thing. One of Jadassohn's most illustrious pupils, the late Professor Bloch, once paid his master an appropriate tribute. "Jadassohn," he said, "is one of those rare persons who, in their scientific publications, actually never make a mistake." Everything Jadassohn wrote bears evidences of having been precisely weighed, maturely considered and thoroughly elaborated. Thanks to his brilliant powers of observation and his stupendous memory, Jadassohn was able to unite the ideology and trends of the Viennese and French schools and those of the aspiring German dermatologists in a happy synthesis. For nearly four decades he directed the work of the German Dermatologic Society and he knew how to make the international conventions of skin specialists interesting gatherings. He acted as German representative on the Committee on Hygiene of the League of Nations. His work principally concerned eczema, skin diseases due to fungi, dermal tuberculosis, leprosy and the venereal diseases. Jadassohn was also known for the publication of the *Manual of Dermal and Venereal Diseases*.

In recent years he had written a textbook of dermatology which to date has not appeared in print, since, after the political upheaval in Germany, Jadassohn was unable to find a pub-

lisher. Departing from professional tradition, the German medical publications have either omitted obituaries of this celebrated research scholar and clinician or have accorded him only a few lines.

#### VIENNA

(From Our Regular Correspondent)

April 27, 1936

#### Freedom of Choice of Physician and Sickness Insurance

With the beginning of the new year the so-called Cooperative Union of Employees' Sick Insurance Societies took up its duties. The new social insurance law stipulates that this corporation shall provide for the three groups of employees' insurance organizations included within it (the commercial, industrial and the financial) the following types of joint service: (1) medical attention, obstetric assistance, dental (including mechanical dental) care, furnishing of therapeutic substances and appliances, (2) arrangement for treatment and nursing in various institutions, (3) settlement of accounts with such institutions as well as with physicians, apothecaries and dispensers of medicaments and appliances, and (4) general supervision of the sick. It will be seen that the Cooperative Union has assumed heavy responsibilities, not one of which is more important than the assurance of medical attention. To facilitate the functioning of this service and place the care of the insured on a firmer basis, provisional agreements were arrived at between the union and the organized medical profession. Payments according to individual professional services were decided on and the lump payment system forthwith abolished. The total cost of physicians' services must now be held to a certain percentage of the total receipts of the three societies. This new arrangement carries with it an advantage to the insured; he may now choose his personal physician from among 258 general practitioners and 114 specialists. The old postulate of "free selection of one's physician" has thus been in great measure realized. An insured person who changes his insurance organization or his position may now retain his *vertrauensarzt* (supervisory medical consultant). Dental needs are the responsibility of the two classes of dentists—practitioners and mechanical dentists. Members of the societies may receive the services of ninety-two of these dentists free of charge. Nominal fees, however, are charged by 244 dentists for the performance of specific work. This new "choose your doctor" system also applies to members of the family of the insured. The patient pays a certain amount to his physician, who then receives the balance directly from the insurance society. Of particular advantage to the doctors are the considerable accumulations of insurance funds now available for every few physicians. From these treasuries the individual doctor receives compensation commensurate with his capabilities. It is now possible for a greater number of physicians to profit from the insurance practice than under the previous lump payment or uniform profits system, which subjected members of the medical profession to something of an economic strain.

At the same time, new regulations were made for the Cooperative Union of Workers' Sick Insurance Societies. The arrangements differ widely from those obtaining in the employees' union. Since the several classes of insured workers pay their premiums into the fund at a lower per capita rate, the number of active physicians cannot be so great or the remuneration so ample as in the employees' insurance. A localizing plan was worked out whereby the exact number of physicians available to the insured workers of each district was determined. Unfortunately, a section of the medical profession under this plan is unable to obtain any insurance patients. It is hoped that in future the work may be so distributed that one physician may confine his activities to

one type of insurance, be it workers', employees', state or municipal. This plan is intended to assure each physician of an income, modest though it may be. Physicians' fees in the workers' insurance have, as in the employees' insurance, been made to conform to a fixed percentage of the corresponding contribution paid in by the insured. According to ordinary calculations some 25 to 30 per cent of the societies' gross income is set aside for the payment of physicians. This means that the doctor receives for single professional services something like 1.20 schillings (25 cents) in the workers' insurance and about 1.60 schillings (32 cents) in the employees' insurance. Specialists receive about double the foregoing amounts. To bring about cooperation between the medical profession and the cooperative union, a "medical commission" has been organized, the membership of which is composed 50 per cent of physicians and 50 per cent of representatives of insurance organizations. Each year the honorarium scale will be computed anew and made to conform to the cash balance at the societies' disposal. Such a system renders the physicians' income rather precarious. The medical commission, in addition to its control of the distribution of physicians' assignments, exercises a much needed power to curtail disbursements for medicaments, cash benefits and hospital care, since such expenditures must come out of that 30 per cent of the gross income set aside for the compensation of physicians. The question of outpatients, heretofore an annoyance to the paid specialist practice, has also been settled. Dental outpatients, together with eye, ear, nose and throat outpatients, are now free to receive treatment from the doctor of their choice and this enables the specialist to carry on an independent practice with steady if modest returns. Since the members of an insured family now are to receive more benefits (this involves some 75,000 persons) a proportionately greater number of physicians will now be called on to serve. These regulations are not to be considered as permanent but as attempts to evolve a system that works. It will require one or two years' time before a condition satisfactory to all can be brought about. Meanwhile one thing is already certain: the incomes of individual physicians will, on the whole, decline and many doctors will find only scant opportunity to carry on private practice. It is hoped that political and religious factors will not exert too great an influence on the operation of the "localizing plan for physicians."

#### Death of Professor Bárány

The renowned otologist Prof. Dr. Robert Bárány, first Austrian to obtain the Nobel Prize for Medicine (in 1914), died in Uppsala, Sweden, his second home, a few days short of his sixtieth birthday. Born at Vienna, Bárány began his studies there and took the degree of Universal Doctor of Medicine (M.D.). He studied at Frankfurt and at Freiburg, and in 1903 returned to Vienna, becoming active first in the surgical clinic and later in the ear clinic of Professor Politzer, then a Mekka for otologists. As early as 1906, Bárány became known to the medical world through the published results of his investigations on nystagmus caused by labyrinthine disturbance in ear disease among normal-hearing persons and in deaf mutism. Not long after he made the discovery of caloric nystagmus and invented the "caloric test," which came to be one of the most important methods of otologic examination. This test together with others discovered by him (Bárány's past-pointing test, Bárány's symptom complex), developed into a whole series of fundamental aids in the localization of cerebral and cerebellar tumors and abscesses as well as of vestibular disturbances. Bárány, more than any other, contributed to our knowledge of the physiology of the semicircular canals. His discoveries, however, were not appreciated in Vienna at the time and he even had to contend with opposition. So, when invited by the University of Uppsala to assume charge of the ear clinic there, he gladly accepted. At

the beginning of the World War he was taken prisoner on the eastern front and it was during his captivity that he was declared a winner of the Nobel Prize for Medicine. The Russians had the generosity (the more striking in view of Bárány's Jewish origin) to allow the eminent scientist immediate freedom so that he might receive the award in person at Stockholm. The honor thus bestowed served to strengthen the ties that bound him to Sweden. In 1917 he became director of the Uppsala clinic. Although in 1909 he had become a docent in Vienna, he first attained professorial rank at Uppsala. Vienna obviously had not considered him worthy of a professorship. In addition to numerous treatises on the labyrinth, written from the standpoints of the physiologist, the surgeon and the sociologist, Bárány was also active as a pacifist and philanthropist. He never allowed his affection for Vienna to wane. This was demonstrated when, thanks to his efforts, the distress among the Viennese physicians after the war was materially alleviated. The Austrian Otologic Society in its most recent session, which took the form of a Bárány memorial meeting, evinced a just appreciation of this man's contributions to medical science.

#### JAPAN

(From Our Regular Correspondent)

April 15, 1936.

#### Mortality in Tokyo

According to the report of the Metropolitan Police Board, the deaths within its jurisdiction (excluding only the islands), have been as follows:

Year	Population	Deaths	Rate per 10,000
1931.....	5,461,628	88,237	161.56
1932.....	5,735,886	80,956	141.14
1933.....	5,877,377	89,370	152.06
1934.....	6,070,880	87,269	143.75
1935.....	6,287,030	85,230	135.56

On an average, from 222 to 247 deaths occur every day, but the general tendency is to decrease in number. In 1936 the deaths included 45,509 males and 39,721 females. The number of deaths of children under 5 years of age was 27,965 (32.51 per cent). The death rate is high in winter and spring, being highest in January; next comes February, December, March and April. Tuberculosis of the lungs was first with 9,876; other tuberculous cases numbered 3,340, a total of 15.50 per cent. Next come 8,121 deaths from pneumonia (9.53 per cent), then 7,922 cases of cerebral hemorrhage. There were 3,688 deaths from cancer, 3,377 from circulatory disorders and 3,048 from kidney diseases. Suicides by means of poison number 538 and by hanging 300. These numbers included 561 men and 342 women.

#### Stray Dogs and Rabies

The authorities have decided to prevent rabies. The hunting of homeless dogs has been loudly censured because of its cruelty, but it had to be done to prevent rabies. Since last year the police tried to castrate homeless male dogs instead of killing them. The Association of Veterinary Surgeons has agreed to aid the police board in the treatment of female dogs. The expense is hereafter to be paid equally by an owner, a surgeon and the board. It is expected that within the year more than 1,000 dogs will be castrated. It is estimated that there are over 50,000 dogs in Tokyo.

#### School Nurses

A remarkable improvement in school hygiene is indicated by an increase of school nurses and school dentists attached to various kinds of schools. This system has been established recently. Of 127 cities, 109 have school nurses in their schools. Formerly it was considered impossible for school teachers to practice the school hygienic laws, because of lack of medical knowledge. In 1934 there were 3,092 nurses throughout the country, an increase of 694 nurses compared with the previous

year. Of these, 806 are graduates from girls' high schools, 2,764 are licensed nurses and 104 are school teachers. The urgent demand for them required the establishment of training institutes with comparatively short training courses lasting for a year here and half a year there and some courses for three months. The course is divided into school hygienics, nursing, bandage dressing, first aid treatment, disinfection, pharmacy, medical instruments, bacteriology, parasitology, dietetics, dentistry, ophthalmology and school hygienic laws. The Education Office is going to organize a central organ to develop school nursing.

#### The Smoke Nuisance

The cloud of black smoke that shoots into the air night and day from 8,924 chimneys in Tokyo has long been a matter of investigation. A regulation controlling the density of smoke is soon to be issued. Last year the cases exceeding the density limit amounted to 1,560, a decrease of 330 cases as compared with other years on an average.

#### Memorial Service to Professor Mendel

Memorial services for the late Prof. Lafayette Benedict Mendel were held in the hall of the Dietetic Laboratory in Tokyo March 24 with Dr. Saeki, the chief of the institute, in the chair. After the opening address by the chairman, Prof. Shigenobu Kuriyama of the Tokyo Imperial University paid an eloquent tribute, recalling his first visit to Yale University in 1916, where he studied under Professor Mendel for a year and a half. He said that his English was poor, which was the cause of much inconvenience, but that Professor Mendel treated him with great consideration. He showed some photographs taken in New Haven. Dr. Takeo Inoue of St. Luke's Hospital, who was under his guidance in 1922, highly admired the noble character of Dr. Mendel. After an address by Dr. Koichi Sugimoto of the laboratory, Dr. Saeki spoke impressively. He recalled that he saw Dr. Mendel for the first time in 1905 at Yale University and that he was the oldest of Mendel's followers living here. He praised Mendel's love for his mother, whom he used to go back home to visit whenever he had any time to spare. He said that he had three ambitions: to write the best book on nutrition, to invite Dr. Mendel to Japan, and to devote his life to science. He greatly regretted that he had failed to accomplish the second. Last of all, as a friend of the deceased, Dr. Kanichi Miyajima delivered the closing address. As Dr. Mendel has so many prominent medical scholars in Japan as his followers, his death is still much lamented here.

#### Death of Prof. Dr. Okajima

Prof. Dr. Keiji Okajima, founder of the anatomy department of the Keio Medical University, Tokyo, suddenly died of apoplexy, April 9, aged 55. He graduated from the Kanazawa Medical College in 1902 and served in the Russo-Japanese War as an army surgeon. After the war he was appointed an assistant in the Tokyo Imperial University and then went to the Kyoto Imperial University and the Nagasaki Medical College as professor of anatomy. When the Keio Medical College was opened he was invited to be chief of its anatomic department. During those thirty years of professorship he devoted his life wholly to the work of anatomy. "The Japanese Anatomy" won fame, for it was entirely written by himself. His later years were given to completing "The Japanese Literature on Anatomy," but his sudden death left it half done. He also painted in oil. According to his will, his bones will be kept in the anatomic department as a specimen.

#### Death of Prof. Dr. Takahashi

Dr. Gonzaburo Takahashi of the Manchurian Railway Hospital died, April 9, in the hospital at Shinking. He was famous for his discovery in 1933 of the cause of Manchurian typhoid, but he was a victim of this disease.

## Marriages

JAMES HAROLD FORRESTER to Miss Jane Eleanor Parker, both of Belleville, Ont., Canada, in New York, May 16.

ROYALE H. FOWLER, Glen Ridge, N. J., to Miss Lillie Marshall Fowler of Montclair, May 9.

JAMES CARR EAGLE, Spencer, N. C., to Miss Sadie M. Ellenburg of Salisbury, May 16.

LEE O. GREENE, Pea Ridge, Ark., to Miss Emma Howard of Cassville, Mo., recently.

ELMER CHARLES KOCOVSKY to Miss Frances Schopen, both of Milwaukee, April 25.

## Deaths

**Edgar Holden Jr.** ♂ Newark, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1899; member of the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; attending orthopedic surgeon to the Newark City, Newark Memorial and Babies' hospitals, and Hospital for Crippled Children; adjunct, St. James and Beth Israel hospitals; consulting orthopedic surgeon to the Hospital of St. Barnabas, Presbyterian Hospital, Hospital for Women and Children, Newark Eye and Ear Infirmary, Newark, Essex County Hospital, Belleville, Mountainside Hospital, Montclair, Muhlenberg Hospital, Plainfield, Irvington (N. J.) General Hospital, Hospital and Home for Incurables, Parental Home and Juvenile Court, Newark Board of Education and the crippled schools, and the Veterans' Administration Facility, Lyons; aged 62; died, April 30, of carcinoma of the lung.

**Augustus Washington Knox**, Raleigh, N. C.; Bellevue Hospital Medical College, New York, 1874; member of the Medical Society of the State of North Carolina; fellow of the American College of Surgeons; at one time professor of surgery, Leonard Medical School and the University of North Carolina School of Medicine; visiting surgeon to the Leonard and St. Agnes hospitals and consulting surgeon to the Rex Hospital and Norfolk-Southern Railroad; aged 87; died, May 9.

**Dwight Wallace Tracy**, West Hartford, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1908; member of the Connecticut State Medical Society; for eleven years medical inspector of the city board of health; for many years on the staffs of the Hartford and Hartford Municipal hospitals, Litchfield County Hospital, Winsted, Middlesex Hospital, Middletown, and the Charlotte Hungerford Hospital, Torrington; aged 52; died, March 22, of arteriosclerosis.

**Theodore William Schaefer**, Kansas City, Mo.; University of Maryland School of Medicine, Baltimore, 1880; professor of analytical chemistry at the University Medical College, Kansas City, 1896-1900, during which time he also taught Latin in the Woman's Medical College, Kansas City; professor of analytical chemistry in the Kansas City Veterinary College, 1900-1906; aged 76; died, March 8, of pneumonia.

**Foster Matthew Johns** ♂ New Orleans; Tulane University of Louisiana Medical Department, New Orleans, 1912; assistant professor of clinical medicine at his alma mater; president of the American Society of Clinical Pathologists; vice president of the Orleans Parish Medical Society; co-author of "Practical Clinical Laboratory Diagnosis"; aged 46; died, April 30, of cerebral hemorrhage.

**Frank Clarendon Cook** ♂ Medical Director, Captain, U. S. Navy, retired, Philadelphia; Harvard University Medical School, Boston, 1893; entered the navy in 1894 and retired in 1933 on attaining age of 64 years; served during the Spanish-American and World wars; aged 66; died, April 20, in the United States Naval Hospital, of intestinal obstruction and chronic myocarditis.

**Benjamin Brittain Simms**, Talladega, Ala.; Jefferson Medical College of Philadelphia, 1885; member, past president and secretary of the Medical Association of the State of Alabama; past president of the Talladega County Medical Society; at one time county health officer and member of the city council; formerly on the staff of the Citizens' Hospital; aged 76; died, March 25, of uremia.

**James Monroe Austin**, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1930; member of the South Carolina Medical Association and the American Psy-

chiatric Association; served during the World War; on the staff of the South Carolina State Hospital; aged 38; died, April 24, of arterial hypertension and chronic nephritis.

**John Samuel Maeder**, New York; New York Homeopathic Medical College and Flower Hospital, New York, 1908; assistant professor of urology at his alma mater; served during the World War; on the staffs of the Metropolitan and Fifth Avenue and Flower hospitals; aged 54; died, April 14, in Mount Vernon, N. Y., of chronic endocarditis and tonsillitis.

**John Joseph Bona**, Chicago; Chicago College of Medicine and Surgery, 1915; member of the Illinois State Medical Society; fellow of the American College of Surgeons; clinical instructor in surgery, Loyola University School of Medicine; aged 43; on the staff of the Hospital of St. Anthony de Padua, where he died, April 25, of pneumonia.

**Read McLane Ellsworth**, Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1924; member of the American Society for Clinical Investigation; associate in medicine at his alma mater; assistant physician on the medical staff of the Johns Hopkins Hospital and Dispensary; aged 37; died, April 28, of pulmonary tuberculosis.

**John Henry Seiler**, Akron, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1886; past president of the Summit County Medical Society; formerly member of the board of education; for many years on the staff of the City Hospital; aged 78; died, March 31, in Southern Pines, N. C., of arteriosclerosis.

**George August Hopp**, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1910; member of the Medical Society of the State of Pennsylvania; formerly associate professor of pathology at his alma mater; member of the American Society of Clinical Pathologists; aged 53; died, April 27, of myocarditis.

**Thomas Jackson Russell**, Somerville, Ala.; University of Alabama Medical Department, Mobile, 1904; member of the Medical Association of the State of Alabama; past president of the Morgan County Medical Society; formerly member of the county board of health; aged 65; died, March 26, of chronic nephritis and uremia.

**Jacob D. Updegrove**, Phillipsburg, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; member of the Medical Society of the State of Pennsylvania; at one time lecturer of hygiene and director of physical training, Lafayette College, Easton, Pa.; aged 73; died, March 22, of arteriosclerosis.

**Thomas Francis Mullen**, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1908; member of the Michigan State Medical Society; fellow of the American College of Surgeons; aged 52; junior orthopedic surgeon, outpatient department, Harper Hospital, where he died, April 13.

**Harold James Connor**, Concord, N. H.; Tufts College Medical School, Boston, 1913; member of the New England Roentgen Ray Society; served during the World War; on the staffs of the Margaret Pillsbury and New Hampshire Memorial hospitals; aged 45; died, April 8, of cerebral hemorrhage and nephrosis.

**Horace Westlake Frink**, Chapel Hill, N. C.; Cornell University Medical College, New York, 1905; member of the American Psychoanalytical Association; formerly assistant professor of clinical medicine at his alma mater; aged 53; died, April 18, in the Pine Bluff (N. C.) Sanitarium, of heart disease.

**James Abram Womack**, Equality, Ill.; University of Tennessee Medical Department, Nashville, 1884; member of the Medical Association of the State of Alabama; past president of the Gallatin County Medical Society; formerly state senator; aged 75; died, March 30, of carcinoma of the prostate.

**James Albert Williams**, Belle Plaine, Iowa; Bennett College of Eclectic Medicine and Surgery, Chicago, 1895; member of the Iowa State Medical Society; formerly member of the city council and board of education; aged 70; died, March 26, in the University Hospital, Iowa City, of pneumonia.

**John Chauncey Van Nuys**, Lufkin, Texas; Rush Medical College, Chicago, 1897; member of the State Medical Association of Texas; formerly president and secretary of the Angelina County Medical Society; on the staff of the Angelina County Hospital; aged 67; died, March 12, of pneumonia.

**Wilgus Bach**, Jackson, Ky.; University of Louisville Medical Department, 1910; fellow of the American College of Surgeons; past president of the Breathitt County Medical Society; owner and medical director of a hospital bearing his name; aged 49; died, April 28, of pneumonia.

**Dawson Dwight Van Osdol**, Rushville, Ind.; Miami Medical College, Cincinnati, 1894; member of the Indiana State Medical Association; past president of the Rush County Medical Society; on the staff of the City Hospital; aged 66; died, March 24, of cerebral hemorrhage.

**Thomas Chittenden Hill**, Boston; University of Vermont College of Medicine, Burlington, 1895; fellow of the American College of Surgeons; consultant to the department of rectal diseases, Boston Dispensary; aged 65; died, April 11, in Vero Beach, Fla., of heart disease.

**Frank Bradbury Hollenbeck**, Lincoln, Neb.; Rush Medical College, Chicago, 1898; fellow of the American College of Surgeons; past president of the Lancaster County Medical Society; surgeon to St. Elizabeth's Hospital; aged 67; died, April 12, of coronary thrombosis.

**Robert Harrison Jeffrey**, Uniontown, Pa.; Jefferson Medical College of Philadelphia, 1912; served during the World War; fellow of the American College of Surgeons; aged 47; on the staff of the Uniontown Hospital, where he died, April 23, of subarachnoid hemorrhage.

**Walter Clifford Chidester**, San Mateo, Calif.; Medical College of Ohio, Cincinnati, 1896; member of the Pacific Coast Surgical Association; fellow of the American College of Surgeons; aged 60; medical director of the Mills Memorial Hospital, where he died, April 21.

**Robert Borden Smiley**, Tripoli, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; served during the World War; aged 58; died, March 28, in the Wisconsin General Hospital, Madison, of coronary sclerosis.

**Edward W. Steeves**, Brownsville, Pa.; College of Physicians and Surgeons, Baltimore, 1898; member of the Medical Society of the State of Pennsylvania; on the staff of the Brownsville General Hospital; aged 68; died, March 24, of angina pectoris.

**James Meriweather Hull**, Augusta, Ga.; University of Georgia Medical Department, Augusta, 1879; member of the Medical Association of Georgia; professor emeritus of clinical ophthalmology and otolaryngology at his alma mater; aged 77; died, April 13.

**Jacob A. Walter**, Punxsutawney, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1887; formerly on the staff of the Adrian Hospital; aged 76; died, March 30, in the Hahnemann Hospital, Philadelphia, of carcinoma of the stomach.

**John Franklin Snyder**, Pittsburgh; University of Pittsburgh School of Medicine, 1931; assistant resident physician to the Municipal Hospital for Contagious Diseases; aged 29; died, March 22, of general peritonitis and cerebral hemorrhage.

**Fred William Robinson**, Sturgis, Mich.; Detroit College of Medicine, 1893; member of the Michigan State Medical Society; aged 68; formerly on the staff of the Sturgis Memorial Hospital, where he died, March 20, of carcinoma of the prostate.

**James Robert Tyner**, Murfreesboro, Tenn.; Washington University School of Medicine, St. Louis, 1934; member of the Medical Association of Georgia; resident physician at the Rutherford Hospital; aged 29; died, March 10, of scarlet fever.

**Daniel John Townsend**, Lohrville, Iowa; Drake University Medical Department, Des Moines, 1887; member of the Iowa State Medical Society; formerly member of the state legislature; aged 80; died, March 27, of heart disease.

**Baylis Frank Sloan**, Walhalla, S. C.; Medical College of the State of South Carolina, Charleston, 1900; member of the South Carolina Medical Association; served during the World War; aged 57; died, March 23, of coronary occlusion.

**William Shaftner Yates**, Junction City, Kan.; Kansas City (Mo.) Medical College, 1893; county health officer; formerly on the staff of the Junction City Municipal Hospital; aged 71; died, March 29, of carcinoma of the larynx.

**Grover Cleveland Davis**, Pelahatchee, Miss.; Memphis (Tenn.) Hospital Medical College, 1912; served during the World War; aged 47; died, March 19, in a hospital at Memphis, Tenn., of pellagra and tuberculosis of the lungs.

**Frank M. Wiley**, Fredonia, Kan.; Starling Medical College, Columbus, 1877; past president of the Wilson County Medical Society; for many years county coroner; aged 80; died, March 12, of cerebral arteriosclerosis.

**William Beatty Lunn**, Marquette, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; on the staffs of St. Luke's and St. Mary's hospitals; aged 63; died, March 28, of heart disease.

**Josiah Lane Sanborn**, Bayonne, N. J.; University of the City of New York Medical Department, 1885; on the staff of the Bayonne Hospital and Dispensary; aged 72; died, March 27, of diabetes mellitus and influenza.

**Robinson Herman Salmon**, Mertens, Texas; Medical College of Alabama, Mobile, 1893; member of the State Medical Association of Texas; aged 64; died, March 28, in the Boyd Sanitarium, Hillsboro, of pneumonia.

**Guy Addison Smith**, Kansas City, Kan.; Fort Wayne (Ind.) College of Medicine, 1905; member of the Kansas Medical Society; aged 53; died, March 17, in the Bethany Methodist Hospital, of chronic myocarditis.

**George Walters Beane**, McKees Rocks, Pa.; Bellevue Hospital Medical College, New York, 1883; member of the Medical Society of the State of Pennsylvania; aged 74; died, March 5, in Lake Worth, Fla.

**Harris E. Timerman**, Chicago; Rush Medical College, Chicago, 1900; member of the Illinois State Medical Society; on the staff of the Swedish Covenant Hospital; aged 59; hanged himself, March 25.

**Francis Henry Davenport**, Boston; Harvard University Medical School, Boston, 1874; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; aged 84; died, April 9.

**Lawrence Madison Small**, Ionia, Iowa; Marion-Sims College of Medicine, St. Louis, 1897; aged 69; died, March 20, of hemiplegia due to cerebral hemorrhage, arteriosclerosis and bronchopneumonia.

**Edgar F. Taylor**, Clinton, S. C.; Medical College of the State of South Carolina, Charleston, 1876; member of the South Carolina Medical Association; aged 83; died, March 27, of bronchopneumonia.

**Howard Franklin Smith**, Hartford, Conn.; Yale University School of Medicine, New Haven, 1896; formerly police surgeon; aged 63; died, March 23, in the Mount Sinai Hospital, of coronary occlusion.

**James Z. Henry**, Ellenwood, Ga.; Atlanta School of Medicine, 1909; member of the Medical Association of Georgia; aged 53; died, March 20, in the Crawford W. Long Memorial Hospital, Atlanta.

**Rawley Martin Shelton**, Unionville, Va.; University of Virginia Department of Medicine, Charlottesville, 1897; member of the Medical Society of Virginia; aged 65; died, March 15, of pneumonia.

**Clark Abbott Stuart**, Castorland, N. Y.; Baltimore Medical College, 1890; member of the Medical Society of the State of New York; health officer of Castorland; aged 68; died, March 15, of erysipelas.

**William Edward Diller**, New York; University of Virginia Department of Medicine, Charlottesville, 1884; University of the City of New York Medical Department, 1885; aged 77; died, March 23.

**Edwin Oscar Swanson** ♂ St. Paul; University of Minnesota Medical School, Minneapolis, 1917; served during the World War; aged 45; died, March 29, of influenza, encephalitis and pneumonia.

**Casius Clay Surber**, Independence, Kan.; Kansas City (Mo.) Medical College, 1884; for twenty-five years chief of staff of Mercy Hospital; aged 75; died, March 8, of mitral regurgitation.

**Willis Edward Lingle** ♂ Cobden, Ill.; St. Louis College of Physicians and Surgeons, 1894; past president of the Union County Medical Society; aged 63; died, March 27, of coronary thrombosis.

**John Henry Phillips** ♂ Willis, Texas; University of Texas School of Medicine, Galveston, 1913; served during the World War; aged 67; was killed, March 11, by an automobile in Houston.

**Edward Buckminster Stephens**, Plymouth, Mass.; Jefferson Medical College of Philadelphia, 1883; aged 85; died, March 24, in Andover, of chronic myocarditis and senile dementia.

**Edgar Speiden**, Silver Spring, Md.; George Washington University School of Medicine, Washington, D. C., 1905; aged 69; died, March 15, of cerebral hemorrhage and cardiac hypertrophy.

**Charles Clyde Tidd**, Mineral Ridge, Ohio; Western Reserve University Medical Department, Cleveland, 1899; veteran of the Spanish-American War; aged 60; died, March 14.

**Claudius Junius Young**, Washington, D. C.; Howard University College of Medicine, Washington, 1915; aged 55; died, March 21, of incised wounds of neck and wrist, self-inflicted.

**Samuel Herbert Stephens**, Saylesville, R. I. (licensed by Rhode Island State Board of Health under the Act of 1895); aged 78; died, March 28, of arteriosclerosis and myocarditis.

**Harry Lincoln Finley**, Taxila, Punjab, India; Jefferson Medical College of Philadelphia, 1895; aged 71; died, March 12, of pneumonia and malignancy of the prostate.

**John T. Hunter**, Equality, Ala.; Birmingham Medical College, 1901; member of the Medical Association of the State of Alabama; aged 71; died, March 22, in Wetumpka.

**Adeline Goodrich Soule**, Kansas City, Mo.; Hahnemann Medical College and Hospital, Chicago, 1890; aged 82; died, March 29, in a hospital at St. Joseph, of senility.

**Ralph Martin Tidd** ♂ Clark, Pa.; Rush Medical College, Chicago, 1902; president of the Mercer County Medical Society; aged 59; died, March 11, of angina pectoris.

**Smith James Townsend**, Gilmore City, Iowa; Western Reserve University Medical Department, Cleveland, 1892; aged 67; died, March 5, of uremia and pyelitis.

**Felix Jefferson Willey** ♂ Mer Rouge, La.; Vanderbilt University School of Medicine, Nashville, Tenn., 1914; aged 45; died, March 26, in Little Rock, Ark.

**Frank Allison Brown**, Stockton, Mo.; Barnes Medical College, St. Louis, 1903; member of the Missouri State Medical Association; aged 56; died, March 13.

**Joseph Milton Wine**, Dayton, Ohio; Chicago Homeopathic Medical College, 1890; member of the Ohio State Medical Association; aged 70; died, March 20.

**Lina M. Rosat**, Lincoln, Neb.; Homeopathic Medical College of Missouri, St. Louis, 1891; aged 72; died, March 17, of myocarditis and hypostatic pneumonia.

**James Arthur Matthews**, Mathis, Texas; University of Louisiana Medical Department, New Orleans, 1873; aged 89; died, March 14, of coronary occlusion.

**Hudson D. Rice**, Dallas, Texas (registered by Texas State Board of Medical Examiners, under the Act of 1907); also a druggist; aged 80; died, March 25.

**John M. St. Clair**, Indiana, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1875; aged 88; died, March 29, of arteriosclerosis.

**Myles Jasper Slaughter**, Millerville, Ala.; University of Alabama Medical Department, Mobile, 1905; aged 65; died, March 19, of pneumonia.

**Francis Marion Trigg**, Freeport, Kan.; College of Physicians and Surgeons, Keokuk, Iowa, 1886; aged 75; died, March 13, of erysipelas.

**Thomas Jefferson Randall**, Los Angeles; University Medical College of Kansas City, Mo., 1899; aged 75; died, March 24, of arteriosclerosis.

**James Semple**, Kibbey, Sask., Canada; Trinity Medical College, Toronto, Ont., 1894; aged 67; died suddenly, March 17, of angina pectoris.

**A. Bromley York**, Huntington, W. Va.; University of Cincinnati College of Medicine, 1924; aged 36; died, March 20, of embolism.

**Thomas Coolidge**, Coalinga, Calif.; Barnes Medical College, St. Louis, 1896; aged 74; died, March 24, of coronary thrombosis.

**George Heinrich Braun**, Fort Smith, Ark.; Eclectic Medical College of the City of New York, 1887; aged 73; died, March 12.

**P. L. Collinsworth**, Atlanta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1897; aged 63; died, March 17.

**Edward Tomlinson** ♂ Orono, Maine; Trinity Medical College, Toronto, Ont., Canada, 1893; aged 66; died, March 24.

**Robert Wilson Claypool**, Mellott, Ind.; Rush Medical College, Chicago, 1881; aged 78; died, March 30.

**John Nelson Stone**, Newark, Ohio; Starling Medical College, Columbus, 1892; aged 67; died, March 17.

**Edward A. Jeffers**, Chuckey, Tenn.; Chattanooga Medical College, 1907; aged 53; died, March 16.

**Byron C. Sorrells**, Mansfield, Ark. (licensed in Arkansas in 1903); aged 70; died, February 24.

**Ransom B. Lynch**, Plato, Mo.; St. Louis Medical College, 1873; aged 90; died, March 8.

## Correspondence

### REVERSIBLE CARDIAC ENLARGEMENT

*To the Editor:*—In his article on reversible cardiac enlargement in *THE JOURNAL*, May 23, Dr. John E. Walker named arteriovenous aneurysm, beriberi and myxedema as the three conditions in which cardiac enlargement may be reduced to normal after specific therapy. To these three I add another. During the past few years we have made extensive studies at the Montefiore Hospital on cardiac enlargement secondary to chronic pulmonary tuberculosis and have observed in several instances the return to normal size, radiographically, of moderately, or greatly enlarged, hearts following the institution of intensive diuretic therapy. In one particular instance a heart which occupied almost the entire chest on x-ray examination was reduced to almost normal size within a month and then went through a similar cycle of enlargement and reduction six months later. Of course, this type of reversible cardiac enlargement is not identical with that described by Dr. Walker because in his cases the reduction in size was accomplished by specific treatment of the etiologic agent, namely, the aneurysm, the beriberi or the myxedema, whereas in our cases treatment was directed only toward the cardiac failure itself and had no bearing on the primary cause of the cardiac enlargement, pulmonary fibrosis secondary to the tuberculous disease. The prognosis in the two types of conditions is entirely different. In Dr. Walker's cases the reduced hearts remain of normal size permanently or as long as the treatment is effective. In the enlarged hearts secondary to pulmonary disease the improvement is only temporary—weeks or months—but eventually the hearts enlarge again and generally speaking the course of illness in these patients is really dependent on the extent and type of the pulmonary disease. In cases of active pulmonary tuberculosis the response to cardiac therapy is insignificant, while in the cases of inactive fibrotic lesions much can be accomplished in the reduction of the cardiac size and the establishment of compensation clinically. The chief point I wish to emphasize, however, is that the cardiac enlargement in pulmonary heart disease, even though extensive, may be reversible with intensive therapy.

MILTON B. ROSENBLATT, M.D., New York.

### "GRANULOCYTOPENIA"

*To the Editor:*—The editorial on "Granulocytopenia, Malignant Neutropenia or Agranulocytosis" published in *THE JOURNAL*, April 25, fails to mention a number of recent articles which have gone far to elucidate some of the mechanisms involved in production of the disease in question.

Most investigators have now accepted the theory first enunciated by Fitz-Hugh and Krumbhaar that the bone marrow of the disease is characterized by a state of "maturation arrest" of the white cells, in which, although the marrow is well stocked with primitive leukocytes ready to mature, the peripheral blood shows depletion of granulocytes. The most complete of recent publications demonstrating this feature is that of R. C. Darling, Frederic Parker Jr. and Henry Jackson Jr. (*Am. J. Path.* 12:1 [Jan.] 1936). These authors point out from study of their large material (mostly biopsies from sternal bone marrow) that the disorder has a rather consistent pathologic picture, which is chiefly characterized by a profusion of young granulocytic cells, the mature cells being conspicuously reduced in number.

What is the mechanism of this "maturation arrest" and why does it occur? Many authors have pointed out that the blood changes may antedate the clinical manifestations of prostration, high fever and mucous membrane necrosis by several days. Sepsis as a factor either general or derived from a local

necrotic process seems therefore very unlikely. As the editorial writer points out, the importance of drugs as etiologic agents has gradually become appreciated in the last few years. Since only a few of the many who have taken aminopyrine or dinitrophenol or arsphenamine develop the disease, the possibility that the disease might be due to an idiosyncrasy, hypersensitivity or allergy to the drug aminopyrine was advanced by several authors. Complete experimental proof of this hypothesis was lacking, however, until publication of an article by William Dameshek and Abraham Colmes (*J. Clin. Investigation* 15:85 [Jan.] 1936). In this study it was shown that in the last series of twelve consecutive patients studied the only consistent etiologic factor was that of a drug, usually aminopyrine, administered either alone or in combination with a sedative. Eight patients of this series recovered and four were intensively studied from the standpoint of a possible allergic reaction to aminopyrine. These four patients when given aminopyrine by mouth in a dosage of from 5 to 50 grains (0.3 to 3.25 Gm.) reacted in varying degrees. One patient, within two and one-half hours after administration of 10 grains (0.6 Gm.) of the drug, developed malaise, pains in all the joints, nausea, and severe headache. In twenty-four hours she had extreme prostration, headache, fever, and a leukocyte count of 1,400, with 28 per cent polymorphonuclear cells. She then developed complete agranulocytosis and finally necrotic lesions of the buccal mucous membranes. After several anxious days, she made a spontaneous recovery.

Scratch tests, patch tests, intradermal tests and passive transfer tests with aminopyrine in all four patients were negative, but striking skin reactions were obtained when intradermal tests were made with a mixture of aminopyrine solution that had been "aged" with human blood serum for several days (controls all negative). This procedure was carried out after the work of F. L. Horsfall Jr. (*J. Immunology* 27:553 [Dec.] 1934) on formaldehyde serum proteins and of Landsteiner on "drug-protein linkage" as a basis for the allergic reaction in certain instances. Not only did these striking skin reactions occur, but two of the patients developed severe hematologic and then clinical agranulocytosis, although the amount of aminopyrine introduced intradermally could not have been greater than 10 mg. (one-sixth grain). Both of these phenomena demonstrated beyond question the great hypersensitivity or idiosyncrasy or allergy of the subjects tested to the drug aminopyrine and suggested a drug-protein linkage as the basis of the "allergic" reaction. That agranulocytosis occurred after intradermal injection of minute quantities of aminopyrine would seem to disprove the contentions of R. R. Kracke and F. P. Parker (*Am. J. Clin. Path.* 4:454 [Nov.] 1934) that "the injection of these drugs, whether it be subcutaneous, intraperitoneal or intravenous, would result in little opportunity for oxidation to the more toxic products, whereas the oral administration of the same drugs . . . would lend them to easy oxidation in the gastro-intestinal tract."

In previous unpublished experiments, Dameshek demonstrated that normal subjects given aminopyrine over a period of from two to four weeks usually developed leukopenia followed by leukocytosis ("release phenomenon") when the drug was discontinued. This suggested that the drug depressed the growth tendency of leukocytes in the bone marrow. Some patients might be so sensitive to the drug that an almost immediate maturation arrest could occur when the drug was given. That this was so was recently nicely demonstrated by Plum (*Ugesk. f. Læger*, 1936, p. 91), who gave aminopyrine by mouth to three patients who had recovered from attacks of agranulocytosis and performed puncture biopsies of the sternal bone marrow both before and after administration of the drug. Coincidentally with the resultant agranulocytosis in the blood, the bone marrow showed large numbers of very immature cells,

only a few mature cells being present. Plum concluded that the leukopenia was the result of a decrease in the production of granulocytes (again "maturation arrest").

The editorial writer states that the mortality is about 92 per cent. This was the mortality rate in 1932 but appears to have become modified considerably since introduction of the nucleic acid derivatives. Of my last twelve patients, all treated with these preparations, nine recovered. In Jackson's large series, about two thirds recovered. Recovery seems to depend on early diagnosis and immediate and massive therapy. In my own hands, greatest success has been obtained with the use of adenine sulfate—a split product of the pentose nucleotides—given intravenously in a dosage of from 1 to 2 Gm. daily or even more frequently.

All will agree, however, that the best treatment for agranulocytosis is prevention. Fortunately the disease seems to be becoming quite rare and this may be due to lessened consumption of aminopyrine both alone and in various sedative combinations. Be that as it may, the whole problem of hypersensitivity, idiosyncrasy or "allergy" to drugs is still a wide open one and will repay much investigation.

WILLIAM DAMESHEK, M.D., Boston.

### HAZARD OF METAL FOIL ON CANDY AND TOBACCO

*To the Editor:*—Your answer to the letter of inquiry from Dr. Charles Stover (*THE JOURNAL*, May 2, p. 1590) regarding the hazards of metal foil on chocolate is timely. Probably the hazard from the use of tobacco packed in foil is quite as great. Recently a bookkeeper, aged 60, consulted me, complaining of self-diagnosed gout. The symptoms and signs were pain in both legs, swelling of the base of the right great toe, and deposits suggesting tophi at the base of the great toe and the second toe. Other symptoms were loss of appetite, extreme nervousness, muscle twitching and mild weakness. According to Peters and Van Slyke, lead poisoning has long been recognized as a cause of gout. They cite Magnus-Levy's thirty-six cases of gout, thirteen of the patients having definite lead poisoning and six others presumably having it. With this in mind the patient was questioned closely as to a possible contact with lead. He stated that for fifteen years he has smoked in a pipe one type of tobacco, which is wrapped in a lead tin foil. The tobacco was in actual contact with the foil, sheets of which measure 17.5 by 25 cm. For purposes of economy the patient has made a practice of saving and selling this foil. Recently he had a pile of flat sheets about 15 cm. in thickness. Before disposing of it he brushed the tobacco from each sheet. There were between one and two hundred sheets, each of which was covered with many little flecks of tobacco and coated in spots with a gray, oily substance, the nature of which has not yet been determined. The salvaged tobacco was then added to the general supply and smoked. Two sheets of the foil and the tobacco pouch were obtained for examination.

The physical examination of the patient was not significant beyond the appearances suggesting gout in the right foot. Pertinent laboratory results were blood uric acid 4.5 mg., no lead line demonstrated at the gum margins, few stippled cells noted in the blood smear, and no abnormal porphyrin in the urine. Two twenty-four hour urine specimens examined by the Ross-Lucas method were found to contain 3 mg. and 1 mg. of lead. The normal lead values for a twenty-four hour specimen range between 0.05 and 0.1 mg. During these tests the patient took 15 grains (1 Gm.) of potassium iodide daily.

A spectroscopic examination was made by Clarence Dupont, spectroscopist of the Strong Memorial Hospital, of the foil, the oily substance observed on it, and the tobacco. With each test lines indicating excessive amounts of lead were noted at wave-

lengths 2,837.32 and 2,833.07 angstroms. A portion of the tobacco taken from the patient's pouch was found to contain 6 mg. of lead per hundred grams, approximately the amount smoked daily. It is estimated by previous investigators that from one fifteenth to one fourth of the lead in tobacco is taken into the body by pipe smoking. This would mean that the patient probably inhaled from 0.4 to 1.5 mg. daily.

The foregoing facts suggest that the patient was definitely poisoned by the lead in the tobacco packed in a foil containing a large amount of lead. The symptoms resulting therefrom presented the clinical picture of gout.

In addition to lead contamination from the foil, there are, in all probability, variable amounts of lead on the tobacco itself caused by the sprays which are used by the growers. Evidence of this fact has been found recently by several investigators. Many of the widely advertised brands of cigarets contain lead in excessive amounts, so that persons employed in an industry or living under circumstances in which they might inhale or ingest small amounts of lead may, by the supplemental lead obtained from the free use of cigarets or smoking tobacco, easily contract low-grade or chronic lead poisoning.

JOHN R. WILLIAMS, M.D., Rochester, N. Y.  
388 Monroe Avenue.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### ACUTE OTITIS MEDIA AND SWIMMING

*To the Editor:*—My son, aged 8 years, last year developed acute otitis media, with spontaneous perforation, from swimming, and the condition completely healed soon after. What measures do you advise to prevent recurrence, if he wants to swim again this year? Please omit name.

M.D., New York.

ANSWER.—In order to prevent a recurrence of acute otitis media due to swimming, it is advisable for the patient not to dive and not to allow water to enter the external auditory canal. The ear may be reinfected in diving by water forcing its way up the eustachian tube. To keep water out of the external auditory canal it is best to block the canal with a piece of sterile lamb's wool and wear a bathing cap. The patient should also be cautioned about blowing his nose violently as swimmers often do in order to free the nasal passages.

### PERCUTANEOUS TUBERCULIN TEST AND TAPE TEST

*To the Editor:*—In *Queries and Minor Notes* in the tuberculosis number of *THE JOURNAL* (Dec. 7, 1935) you mention the percutaneous method tuberculin test (described by Beatrice Lovett) and the tape test (described by Ernst Wolf). Will you please give me the technic and source of material for both these tests? Kindly omit name.

M.D., Arizona.

ANSWER.—The percutaneous method of administering tuberculin described by Lovett (*Am. J. Dis. Child.* 37:918 [May] 1929) is a modification of the Moro test. It consists of rubbing the skin over the region of the sternum with ether in order to remove all oil from the pores. This is accomplished when hyperemia appears. To this area is applied a piece of concentrated old tuberculin about the size of a pinhead, which is rubbed into the skin with the fingers. If the test is negative, the skin will appear normal at the usual time of reading the test; that is, in about forty-eight hours. If the test is positive, a definite reaction will be seen at this time to consist of papules scattered about the area but there may be little or no reddening of the skin. A marked reaction, however, consists of folliculitis, with small vesicles or pustules and intense inflammation of the skin. The material employed by Lovett is manufactured and dispensed in collapsible tubes by Dr. Fresenius, Hirsch Apotheke, Frankfurt-on-Main. However, other tuberculin ointments are now available for this test.

The tape test of Wolff (*Am. Rev. Tuberc.* 27:308 [March], 1933) consists of cleansing the skin in the paravertebral region between the eighth and eleventh thoracic vertebrae with green soap and water. When dried, the area is bathed with benzene. After drying again, a drop of tuberculin ointment the size of a pea is applied over the right side of the cleansed area and on the left side a drop of control ointment is used. Both drops are then covered with pieces of adhesive tape two inches square. This is tightly applied. In forty-eight hours the tape is soaked with benzene and removed. Ten minutes later the reaction is observed. When positive, the area over which the tuberculin ointment was applied shows papules, erythema, induration and pigmentation. He finds that this test is generally comparable in results with the intracutaneous test in a dilution of 1:100. The ointment used for this test was devised by Wolff of the pediatrics department of the University of California Medical School and was especially prepared for him. It contains a highly concentrated tuberculin and killed tubercle bacilli incorporated in an ointment base that is able to penetrate into the cutis.

#### TREATMENT OF GONORRHEA

*To the Editor*—A male patient contracted gonorrhea in 1912 and after having received injections of silver nitrate, massages and sound treatments for two years was discharged as cured. In 1917 sickness recurred. It might also have been reinfection. He received about the same treatment as before without result, until in 1919 he engaged the services of a university professor, who discharged him as cured after two months of treatment. A year later, in 1920, he again had a discharge, and the general feeling was bad. After a few months of treatment by the same professor, he was discharged again as completely cured and allowed to get married, which he did that same year, and has four healthy children. He felt well until 1932, when symptoms of occasional discharges, mostly mucous, and general bad feeling reappeared. Physical examination revealed a small nodule in the right epididymis. The prostate was normal in size and moderately firm in consistency. The seminal vesicles were somewhat thickened, the right considerably dilated and indurated. Discharges and fluids obtained by prostatic massage were frequently examined and showed numerous pus cells but no gram-negative diplococci. On cystoscopic examination the instrument passed with some difficulty because of a tight posterior urethra. The interurethral bar was large and somewhat enlarged, otherwise the results were normal. A roentgenogram was negative. The patient received a series of treatments consisting of prostatic massage, urethral instillations and bladder irrigations, vaccine and foreign protein injections. The patient appeared to be comfortable for a few weeks, when the symptoms recurred much to his dismay. I would appreciate any suggestion for treatment of this case. Kindly omit my name.

M D, New York.

*ANSWER*—The urethral discharge in 1917, if it was gonorrheal, undoubtedly was a new infection. The probable reasons for continuance of trouble for two years were either the patient's conduct or overtreatment. The professor's ready success was probably due to the fact that he controlled the patient and used either milder or no local treatment. It is probable, however, that the patient was left with an infected prostate, which in 1920 caused a urethral discharge which was not gonorrheal, and the professor, knowing that it was not gonorrheal, had no reason to interdict matrimony.

The clinical picture starting with 1932 is not so clear. There are features suggesting long-standing prostatic infection and, on the other hand, if the clinical observations are correct, it could be due to tuberculosis. The latter is suggested by the nodule in the epididymis, induration of the seminal vesicle and the "tight posterior urethra." If the patient had an attack of epididymitis previously and the nodule in the epididymis is in the lower pole, the epididymal condition is in all probability not of tuberculous origin. If not, and the nodule is in the upper epididymal pole, this disease merits serious consideration. Seminal vesicular palpation is fraught with so many possibilities for error that what seems fibrosis to one is to another merely tissue density normal to the individual. It is rare that tuberculosis of the prostate of sufficient degree to give the impression of tightness on the passage of an instrument does not cause nodulation of the gland. Thus, the first most important thing is to rule out that disease. Otherwise grave harm may be done by forms of treatment appropriate to other diseases.

The repeated attacks of urethral discharge, whether or not gonorrheal, the large amount of pus in the prostatic secretion, "the tight posterior urethra," and the enlarged interurethral bar all bespeak marked prostatic infection. If tuberculosis is ruled out, this probably started as the result either of gonorrhea or of the treatment, though one should not lose sight of oral infections, teeth or tonsils, as possible factors.

So far as treatment is concerned, tuberculosis being ruled out, it is probable that no amount of prostatic treatment will render such a gland pus free. Much, however, may be done for the prevention of possible arthritic or other focal infective

conditions by occasional digital drainage of the gland by rectum. Such patients frequently are candidates for median bar formation and should be observed from year to year with that in mind.

The age of the patient is not mentioned but, so far as the nongonorrheal discharge is concerned, some comfort may be gained from the fact that such discharges from any cause are rare after 40 years of age and almost do not occur after 45.

If local treatment for the urethral discharge is carried out it should be with half strengths of any of the substances generally used for that purpose, to avoid the building up of protective squamous surfaces, later to shed and cause more urethral discharge.

#### IRREGULAR VAGINAL BLEEDING AND ENDOCRINOLOGIC TREATMENT

*To the Editor*—My wife, now 44 years of age, who has always been a normal, healthy woman with regular menstrual periods, is now approaching the menopause. Menstruation has been irregular for the past few months and the period is longer than normal. Also she is rather nervous at this time for the first time during our twenty-three years of married life. I am an internist and have very little knowledge of what can be done to make this period of her life as normal as it should be. I do know, however, that much can be done and am asking you for information and advice. Will you please let me know what medicines, if any, should be given? I know that ovarian extracts are used, also I see "Ergoaprol," made by Martin Smith, which is freely advertised. Is this an "accepted" article? Please advise me and refer me to any pertinent literature.

M D, South Dakota

*ANSWER*—In general there are three types of irregular vaginal bleeding at the menopause. First, there is bleeding which corresponds to a normal menstruation but which occurs not at the usual interval of approximately twenty-eight days but at multiples of this interval; that is, every two, three or four months. In other words, the patient is menstruating normally except that some periods are skipped completely. Irregularity of this type usually has no serious significance, but it should be carefully watched and, if it persists, cancer should be suspected. The second type of bleeding is metrorrhagia; the periods occur at the usual intervals but the amount and duration of the flow are variable and excessive. Such irregularity is commonly the result of endocrine disturbances of a benign nature but occasionally is the first indication of carcinoma of the corpus uteri. The third type of irregularity is metrorrhagia, or bleeding between the menses. By common usage metrorrhagia signifies uterine bleeding occurring at unpredictable intervals, with no regularity of duration or amount. Such bleeding is of the gravest significance. While it may be the result of relatively harmless disorders (retained secundines, polyps, endocrine disturbances), the physician bears a heavy responsibility until the diagnosis is assured. Particularly in women of middle age is metrorrhagia ominous, for they are in the "cancer period" and metrorrhagia is the chief sign of early carcinoma of the cervix.

Therefore the physician consulted by a patient in the forties because of "irregular menstruation" must be continually on guard and should advise biopsy of the cervix and curettage if he has any sound suspicion of cancer. Treatment is not permissible until cancer has been ruled out by biopsy, curettage and histologic examination. Since endocrine preparations have generally been of little value in correcting menopausal metrorrhagia, castration by radium or x-rays (preceded of course by curettage) or hysterectomy is usually employed when the bleeding must be stopped. It is hardly necessary to add that postmenopausal bleeding should excite fear of cancer and demands thorough investigation at once.

The results of endocrine therapy in the treatment of vasomotor instability, nervousness and other subjective manifestations of the menopause have been discussed in *THE JOURNAL*, by Sevringhaus (Feb. 23, 1935, p. 624), Frank, Goldberger and Spielman (Aug. 11, 1934, p. 393) and Novak (May 18, 1935, p. 1815, Aug. 31, 1935, p. 662). Although Frank has been skeptical of the results of such treatment, most writers believe that the use of estrogenic substances is logical and of distinct value. Kurzrok (*Endocrinology* 16:361 [July-Aug.] 1932) has studied the rate of excretion of estrogenic substance during the menopause and believes that replacement therapy is indicated when estrogenic products are not being excreted in the urine. Since it is not possible in general practice to determine the rate of excretion, patients are usually treated empirically. Novak recommends a dose of from 100 to 200 rat units daily (theelin, thelol, ammotin oral, progynon). This dosage applies if the administration is parenteral, the dose by mouth is five times as great.

Since the use of the drug is empirical, the dose should be increased until the desired effect is obtained. Provided carcinoma of the uterus has been ruled out, as it must be before treatment is begun, no danger is involved with these dosages.

Uterine bleeding may be a concomitant of the endometrial hyperplasia that results from the estrogenic drugs, and undesirable stimulation of the libido may be noted. If so, the dose should be decreased. If the flushes and nervousness diminish satisfactorily, the dosage should be gradually lowered and maintained at the empirically determined optimum level. None of Sevringhaus's ninety-five patients required treatment more than thirty months. The use of mild sedatives over long periods is recommended in conjunction with the endocrine therapy.

"Ergopioli" is an irrational mixture rejected by the Council on Pharmacy and Chemistry in 1914. The discussions of Sevringhaus and of Biskind (*THE JOURNAL*, Aug. 31, 1935, p. 667) furnish detailed information on estrogenic substances now on the market.

#### FUNCTIONAL VOMITING

*To the Editor*—A woman, aged 20, came to me for treatment in June 1935 with a complaint of vomiting without nausea within an hour after meals. She had been under treatment for three years by other physicians without improvement. The first time she vomited was in high school when she found she had a Latin teacher she did not like. She gradually began to vomit more frequently and sometimes vomited all three meals. She lost about 20 pounds (9 Kg.). She was vomiting all her meals when she came to me. She does not vomit water or candy. The patient is slender and weighs about 100 pounds (45 Kg.). Physical examination was essentially negative except for rather faulty posture. Blood pressure was 98 systolic, 66 diastolic, with a pulse of 87. A gastro-intestinal x-ray series showed a normal functioning stomach and intestine but a pronounced visceroptosis. There was no spastic condition of the pyloric valve. Roentgen examination of the esophagus showed the valve at the cardia to be half that of normal in its longitudinal measurement. Esophagoscopy showed nothing unusual. The basal metabolic rate was minus 10. The patient was put on six small dry meals a day. Fluids were given half way between feedings. She elevated the foot of the bed 12 inches. She wore a corset for correction of the visceroptosis. By August (three months) she was improved to such an extent that she would go two weeks without vomiting. Owing to warm weather (and without my consent) she quit wearing the corset. Vomiting became more frequent. During the summer she had irregular menstrual periods, sometimes missing one or two. During September and October I gave her injections of anterior pituitary, estrogenic substance and corpus luteum. Her menstrual cycle is normal now. She has bilateral tenderness in the lower quadrants. The hymen is intact. There is a rather profuse vaginal discharge, mucoid in character. She is sensitive to belladonna in dosage above six drops. She thinks her vomiting is of little less frequency when taking that amount. I have not done a gastric analysis. If you have any suggestions on treatment of cases of this type, I shall be glad to get them. Do not publish my name, please.

M D, Ohio

**ANSWER**—From the description presented, it appears probable that the patient's symptoms are not due to gross organic pathologic changes either of the central nervous system or of the gastro-intestinal tract. As to the latter, there are no data suggestive of malignancy, chronic cholecystitis or gastric ulcer, nor is it likely that the vomiting can be attributed to visceroptosis, since a descent of the viscera of sufficient degree to cause emesis could not be corrected by an abdominal belt. Further, the rare possibility of a visceral constriction by a congenital peritoneal band, although not ruled out by an x-ray series done with the usual technic, is nevertheless incompatible with the comparatively late onset of the patient's symptoms or with their improvement under what seem to have been essentially suggestive measures of therapy. It would appear likely, then, that the patient's vomiting is of so-called functional origin. In this event, specific treatment of the symptoms alone can produce only a temporary amelioration, since a broader evaluation of the patient's personality and problems is essential for effective therapy. In the absence of more detailed information, it is of course idle to speculate as to the possible psychodynamic mechanisms underlying her illness; these can be discovered and treated only after careful investigation by a competent psychiatrist.

#### CIRCULATORY DIFFICULTIES IN ARTERIOSCLEROSIS

*To the Editor*—A man, aged 45, has arteriosclerosis of the legs and feet due to diabetes, discovered recently. He feels well otherwise, he wants to walk but suffers greatly several hours after walking. What other exercise, active or passive, can he take? What can be done to relieve pain after walking? What are the possibilities of establishing collateral circulation and how could that process be assisted? Please omit name.

M D, New York

**ANSWER**—It is important to know whether or not the arteriosclerosis indicated has caused occlusion of the main arteries to the extremities. This can be determined by palpation of the dorsalis pedis, posterior tibial and popliteal arteries for pulsations, notation of color changes when the feet are elevated and dependent, and estimation of the warmth of them.

Absent or diminished pulsations, abnormal pallor resulting from elevation, abnormal rubor resulting from dependence, and unusual coldness of the feet indicate occlusive arterial diseases.

Conversely, normal or nearly normal pulsations, minimal color changes resulting from change of posture and warm feet indicate adequate arterial circulation. Intermittent claudication is a type of distress frequently resulting from arterial insufficiency. It is produced characteristically by exercise and relieved in a few minutes by rest. It is improbable that the distress mentioned by the correspondent is intermittent claudication, as it persists long after discontinuance of walking. However, the patient should be questioned carefully about the distress. Intermittent claudication has been treated with extracts of pancreas (insulin free) or of skeletal or heart muscle (Barker, Brown and Roth: *Tr. Am. Therap. Soc.* 33:115, 1933; *Am. J. M. Sc.* 189:36 [Jan.] 1935) or with intermittent negative and positive pressure as indicated by Herrmann and Reid and by Landis, reviewed by Allen and Brown (*THE JOURNAL*, Dec. 21, 1935, p. 2029). The last mentioned method may be valuable in establishing collateral circulation. Contrast baths, postural exercises and radiant heat and the intravenous injection of typhoid vaccine may aid likewise (Brown, G. E.: *Thrombo-Angiitis Obliterans, Surg., Gynec. & Obst.* 58:297 [Feb.] 1934).

Diabetic neuritis must be considered in the diagnosis of the condition of the correspondent's patient. Usually there are manifestations of nerve injury, as diminished muscle strength, tendon reflexes or sensation. Frequently evidence of inadequate arterial circulation is likewise present. This is occasionally a very difficult condition to treat satisfactorily. Control of the diabetes is important. Measures to increase the circulation are indicated if the circulation is less than normal. Irradiation over the lumbosacral area by an experienced roentgenologist may diminish the distress. Recently, concentrated vitamin B has been found to be of value. A trial of it is certainly worth while.

#### INFERTILITY AND PRODUCTION OF SPERM

*To the Editor*—I am not a urologist but an eye and ear specialist. I am interested in a very famous dog, with one exception probably the most prepotent sire of his breed ever imported into America. This dog is now not quite 5 years old. During his first two and a half years he was a prolific sire and in his stud career produced many great show winners. Without illness and without overwork, he suddenly began to miss with his bitches until he finally ceased entirely to produce pups, at about 3½ years of age. His desire is as normal as ever and his copulating ability unimpaired. This sterility seemed to be coincident with an atrophy and softening of the testicles. It was then noted that the testicles appeared unusually small compared with other dogs of his breed, but men vary in this particular and it may have been that the organs were always small. The dog was sent to the kennel of a professor of veterinary medicine in Toronto, where he remained about eight months, being given special attention in feeding, in the hopes that change of climate and so on might improve him. He was mated to half a dozen bitches in succession, with negative results. The professor used no sexual stimulants. As dogs are used in laboratories because their diseases and reaction to drugs are similar to those of men, I would ask: 1. Is there ever in mature life an atrophy of the testicles due to disease? 2. Are men in the prime of life (known to have been fertile) ever subject to such infertility as has come to this valuable dog? 3. Is there any remedy, not empirical, known to urologists, that will stimulate the production of spermatozooids? 4. Is there any explanation for the continuance of this dog's copulative virility and of the disappearance of spermatozooids? Such urologic books as I have consulted do not enlighten me on these questions. The professor in Toronto reported, after examination, absence of spermatozooids. Please omit name.

M D, Louisiana

**ANSWER**—1 and 2. Yes. Several conditions, among them high febrile states, lead to some testicular diminution and loss of spermatozoa in man. Usually, perhaps, recovery may be expected to follow disappearance of the inciting cause, provided testis injury is not sufficiently great to have eliminated spermatogonia from the testis. It has been assumed, with apparently good grounds, that business worries or other psychologic states may sometimes be accompanied by temporary azoospermia. In highly pedigreed stock (especially stallions and jacks) great difficulty is experienced in keeping them in good breeding condition.

3. Remedies thus far attempted fall largely into two general classes: (a) nutritional and (b) endocrine. Proper food and exercise outdoors have been greatly emphasized. It is known that dogs confined to laboratory cages and fed well may lose temporarily the capacity to produce spermatozoa. Wheat germ oil has been tried as a supplementary dietary factor. Endocrine treatments have been largely restricted to introduction of gonad-stimulating substances. Reports on human cases of male sterility suggest occasional beneficial results from treatments with injections of the gonadotropic principle of pregnancy urine. Daily injections of 100 to 500 rat units for a few weeks might prove efficacious in restoring spermatozoa to the discharge.

4. There are many cases in which spermatozoa are not formed and yet copulative ability is retained. Such is true for all naturally occurring cryptorchids (undescended testes) in which both testes are retained in the abdomen. The germ cells, so far as known, do not contribute to the internal secretion of the testis which is responsible for inciting the copulatory drive.

#### IMPLANTATION OF GOLD SPHERE IN TENON'S SPACE

*To the Editor:*—Is the operative procedure of implanting a gold sphere in Tenon's space one that is generally accepted by the medical profession and used by leading ophthalmologists? It is my understanding that this procedure is considered safe so far as the health and life of the patient are concerned, and that it is generally accepted as a constructive technic for better cosmetic results when an eye has to be enucleated. I have never known any complications to arise other than the occasional loss of the gold sphere from the orbit at a later date. My reason for proposing this question is that a number of months ago I enucleated an eye for a patient and implanted a gold sphere. It was a clean case. There were no complications. The cosmetic result was good and there was good motility of the artificial eye. I am now the defendant in a \$50,000 malpractice suit in which the plaintiff alleges that it was wrongful to implant the gold sphere and that six months later it was necessary for him to have the gold sphere removed in order to save his life. I was not informed by the other ophthalmologist of any trouble with the orbit. This man rushed the patient to the hospital and removed the sphere. The first information that I received about the removal of the sphere was when the sheriff served me with the court summons.

M.D., Indiana.

*ANSWER:*—The implantation of a gold ball has been practiced since it was first proposed by Webster Fox in 1902. Numerous articles recommending that technic have appeared, particularly by Greenwood (*Arch. Ophthalm.* 43:1, 1914), Dimitry (*Am. J. Ophthalm.* 2:653 [Sept.] 1919), Carrasco (*Zentralblat. f. d. ges. Ophthalm.* 1921) and others. In general, the procedure is recognized by ophthalmic surgeons throughout as a legitimate, safe procedure. It is impossible to conceive of any condition occasioned by the gold sphere that could endanger the life of a patient. If a malignant tumor had developed in the orbit, in no way could it be attributed to the presence of the gold sphere. It is suggested that an endeavor be made to find out why the other ophthalmologist considered it essential to rush the patient to operation "to save his life."

#### THE CONSTITUENTS OF TOBACCO SMOKE

*To the Editor:*—Does smoking tobacco have any proved effect on the thyroid or on thyrotoxicosis? Does tobacco contain iodine? Also please state if possible why so many people gain weight rapidly after discontinuing tobacco.

DENVER F. GRAY, M.D., Rusk, Texas.

*ANSWER:*—Dr. Walter A. Bastedo in his article "What the Physician Should Know About Tobacco" says that in some cases of hyperthyroidism the use of tobacco raises the basal metabolism. None of the several available publications that discuss the constituents of tobacco make any reference to the presence of iodine in tobacco smoke. In addition to nicotine and its derivatives, tobacco smoke contains such toxic substances as pyridine, thiotetrapyridine and isodipyridine, prussic acid, pyroline, ammonia, collidine, formaldehyde and carbon monoxide. In his book "Tobacco and Physical Efficiency: A Digest of Clinical Data," Pierre Schrupf-Pierron quotes other investigators to the effect that collidine is more poisonous than nicotine, although there are only traces of it in tobacco smoke. The smoke of ten cigars, this author notes, contains from 4 to 5 mg. of prussic acid. The smoke of 1 Gm. of tobacco contains from 0.9 to 1.2 mg. of pyridine, thiotetrapyridine and isodipyridine; investigators differ as to whether these products share in the poisonous effects of tobacco. One gram of tobacco yields from 3.22 to 5 mg. of ammonia. The formaldehyde in tobacco smoke, combined as it is with the nicotine, is said to diminish the toxicity of the smoke. Authorities agree that carbon monoxide is one of the most harmful elements of tobacco smoke from a practical point of view. Baumberger found that tobacco smoked as cigarettes yields about 8.3 cc. of carbon monoxide per gram of tobacco smoked and that about 61 per cent of the carbon monoxide is absorbed, if the smoke is inhaled.

It is not necessarily true that people gain weight rapidly after discontinuing the use of tobacco. In some persons tobacco lessens the appetite and the pangs of hunger; when not habituated to tobacco, such persons naturally would eat more food, and that may account for their increase in weight after discontinuing the use of tobacco.

#### CHRONIC ENDOCERVICITIS

*To the Editor:*—What are the possible causes of a persistent mucopurulent (predominantly mucoid) discharge from the cervix uteri, of eight months' duration, in a white woman, aged 30, with a ruptured hymen (but whose other pelvic organs appear to be normal to bimanual examination), with a normal menstrual history except for a prolonged interval of about three weeks, one year ago. The discharge is negative for gram-negative diplococci and *Trichomonas* on repeated examination. The cervix bleeds slightly when the mucus is removed too thoroughly with a cotton applicator. A biopsy was negative for evidence of malignancy. The discharge did not disappear on endocervical coagulation, although a concomitant erosion did. Are there any factors above the cervix that might be responsible? In what manner does the sex life influence such discharges aside from infection? Would you recommend ionization with a surgical diathermy electrode?

M.D., Pennsylvania.

*ANSWER:*—The patient has endocervicitis and the infection is probably persistent because of inadequate drainage.

The etiology of such infections is not only of interest but also of therapeutic importance. In the case of gonorrheal disease it is seldom possible to identify the gonococcus in the cervical discharge after the early weeks of infection. In establishment of a diagnosis, a history of exposure and demonstrable infection of Skene's ducts and/or the Bartholin glands affords more dependable evidence than search for the gonococcus, although the latter is not to be deprecated.

Postabortive infection, cervical lesions incident to childbirth, and instrumentation and medication of the cervix in attempted relief of various disorders are other common causes of persistent mucopurulent leukorrhea.

As stated, in the majority of instances the discharge persists because drainage is inadequate. There may be gross obstruction of the cervical canal or, more frequently, there are microscopic pockets that fail to drain. Endocervical cauterization owes its efficiency to establishment of drainage rather than to eradication of the cervical glands.

Infection above the level of the cervix is seldom responsible for a persistent discharge; even in the case of pyometra an obstruction of the cervix is usually the primary cause of the trouble.

In the treatment of persistent mucopurulent cervical discharge a Hegar dilator should be passed to make certain whether the canal is sufficiently patent. Granted that there is no demonstrable gross obstruction, radial endocervical cauterizations with a nasal tip cautery may suffice to effect a cure. Some prefer endocervical coagulation. In the event that these measures fail, amputation of the cervix, or even a complete hysterectomy, may be necessary in extreme cases.

#### SENSITIVITY TO CHICKEN AND EGGS

*To the Editor:*—I find that I am sensitive to chicken and all products, as severe gastro-intestinal symptoms follow the eating of chicken or eggs in all forms, and the exposure to feathers or dust of a coop brings on severe congestion of the conjunctiva, asthma, and later, as the bronchial mucus is swallowed, the familiar gastro-intestinal symptoms. Is there anything I can do to develop an immunity? My literature is either barren or so voluminous that the grain of truth is lost in the mountain of chaff.

M.D., San Francisco.

*ANSWER:*—The antigens of chicken, eggs and feathers are not related, although one of the proteins of egg white is the same as one of those found in chicken serum. Clinical sensitivity, therefore, to these three antigens in the same person should be considered probably as a coincidence, and treatment should be directed to each one of the three separately.

The simplest and probably the most effective treatment against all three of these antigens is their complete elimination from the individual's diet and environment. Any food containing even a trace of egg, for instance, should be avoided. After such complete elimination for a year or more, the result is frequently an increased tolerance to the food so that small amounts, as, for example, the amount of egg used in baking and cooking, may be tolerated.

Oral immunization to foods may be tried when elimination is not possible. Several forms of oral immunization have been tried. First, the feeding of a minute amount (i. e., two or three drops of egg white, in relatively low grade cases of sensitivity) about one half to three quarters of an hour before the meal containing the antigen responsible for the trouble. This has been discussed by K. P. Eiselsberg and F. Kauders (*Wien. klin. Wchschr.* 47:679 [June 1] 1934), who give extensive references. Another method is that of the feeding of specific propeptan before the meal (Urbach, Ehrlich: *Skin Diseases and Nutrition*, Vienna, Wilhelm Mandrich, 1932). A third method is to start with a very dilute solution of the antigen, increasing the dosage very gradually every third or fourth day and always

keeping below the dose that produces a constitutional reaction (Rackemann, F. M. *Clinical Allergy*, New York, Macmillan Company, 1931, p. 313 and following)

Injection of food antigens is dangerous and is not to be recommended for use except by a worker trained in allergy

If feathers cannot be completely avoided, subcutaneous injections for hyposensitization are advisable. These should be given very gradually, starting with a dilute solution

#### CORPUS LUTEUM CYST

*To the Editor*—A white woman, aged 22, single, a school teacher, weighing 125 pounds (57 Kg) and 5 feet 6 inches (168 cm) in height, complains of pains in the stomach intermittently before menstruation starts, the periods are irregular, scanty, of one to two days' duration, and accompanied by cramps at times. Recently I was called to see her. The temperature was 98.6 F, the pulse 60. She was complaining of cramps in the lower part of the abdomen with pains going to both shoulders aggravated to such an extent by changing position that she screamed with pain. The woman was well developed, was a brunette and had numerous large coarse black hairs from the symphysis to the umbilicus, with tenderness over the tubes and bladder and marked tenderness over the pit of the abdomen. Otherwise the physical examination was essentially negative. In four fours I was called to see the patient again. This time she was complaining of shortness of breath and marked distention of the stomach with pyrosis, nausea and vomiting. The temperature was 97, the pulse was 120 and the hands and legs were covered with a cold clammy sweat. I washed out her stomach, gave her a purgative and corpus luteum 1 cc intramuscularly and advised fluids and heat. Later in the afternoon I saw the patient again. She was resting much better. The temperature was 98.6 the pulse 120. The next day she began to menstruate. She was much improved. The following day she came to my office. The blood count was 6,750 leukocytes, 3,300,000 erythrocytes, hemoglobin 75 per cent and the urine was normal. The patient's mother died of cancer about two years ago. What is the diagnosis of this case and the physiologic mechanism back of the trouble? Is there a possibility of a neoplasm at her age? What treatment would you advise? Does one have to consider acute pancreatitis? The patient has had a number of these attacks before her periods, but none so severe, and in none has she had such definite symptoms of shock. The patient had always been in good health before these attacks started and has been gaining in weight. Please omit name. M D, Missouri

*ANSWER*—One must consider particularly the presence of a corpus luteum cyst because of the premenstrual disturbances, and the possibility of rupture at the time of the symptoms of shock. Sometimes the rupture of the cyst may lead to spontaneous cure, or again the cyst may recur. No note is made of a rectal examination. The result of such an examination revealing a cystic enlargement is valuable in the diagnosis. Other types of pelvic disorder may be present. It would be advisable to have a pneumoperitoneum made and an x-ray film of the pelvic organs for further elucidation.

#### LOW SPECIFIC GRAVITY OF URINE

*To the Editor*—What is the significance of a urinalysis with specific gravity of practically 1.000 the last fifteen years with no albumin or other gross abnormality, and with the color almost like that of water? The patient is now past 82 years of age. He has never had any serious illness and apparently is in perfect health with the possible exception of slight prostatic enlargement necessitating arising once or twice a night for urinating, sometimes but not always. Does low specific gravity always mean abnormality? I am the patient. Please omit name.

M D, South Dakota

*ANSWER*—The normal urine volume and specific gravity are a function of the fluid intake and of the amount of loss of fluid either by perspiration or from the lungs and intestinal tract. The total solids excreted daily are somewhat less variable and average about 60 Gm. As a result, the specific gravity tends to vary in inverse ratio to alterations in volume. The normal range of specific gravity in this country is about 1.008 to 1.028. The specific gravity decreases with increased intake of fluids. However, it never drops to 1.000. Such a reading indicates the use of an inaccurate urinometer. In diabetes insipidus, associated with a lesion in the posterior lobe of the pituitary gland or the adjacent area of the brain, the patient may secrete from 3 to 30 liters of urine with a specific gravity as low as 1.001.

A low specific gravity of the urine, except in diabetes insipidus, does not alone indicate any abnormality. If the kidney function is normal, the avoidance of fluids for twenty-four hours should cause the specific gravity of the urine to rise to 1.025 or higher, and the drinking of from 1,200 to 1,500 cc of water should cause a drop to 1.003. The specific gravity of the urine in itself is the most useful single test of renal efficiency and plays an important part in the concentration and dilution tests of kidney function.

#### USE OF MANGANESE IN HYPERGLYCEMIA

*To the Editor*—Please inform me whether there is any scientific back ground for the use of manganese dioxide in the treatment of hyperglycemia with glycosuria. I have a patient who had from one to four plus sugar in the urine regularly before she began taking manganese dioxide, 5 grains (0.3 Gm), after each meal. The urine is now free from sugar but she feels rather weak. What is the probable explanation of this? Could it be due to the manganese dioxide she has been taking? How long is it safe to administer manganese dioxide in 10 to 15 grain (0.65 to 1 Gm) doses daily? Is there any danger of ill effect of any nature and, if so, what are the usual initial symptoms? Please omit name.

M D, Georgia

*ANSWER*—Manganese resembles iron in that it is absorbed with difficulty and eliminated chiefly in the stools. Chronic manganese intoxication has thus far been observed only in workmen exposed to massive inhalation of manganese dust. It presents a symptom complex of muscular weakness and tremor, resembling somewhat that of parkinsonism but often accompanied by psychic disturbance. The condition has not been reported from the medicinal use of manganese. Experiments on rabbits have proved negative as to any effect on carbohydrate metabolism. It is only when such animals were subjected to chronic poisoning by subcutaneous injections of manganese sulfate that hypoglycemia was produced, to a marked degree only in the terminal stages. Without data as to the patient's diet it is impossible to evaluate the observation recorded. The patient should be treated by the proper and adequate ingestion of suitable food and the care of the diabetic condition along accepted lines.

#### DIAGNOSIS OF UNUSUAL ERUPTIVE DISORDER

*To the Editor*—A boy, aged 11 years, gives a negative history except for an attack similar to the one from which he is now suffering, about a year ago, which lasted for three months. He is robust and physically normal with the exception of 1 degree of elevation in temperature. There is no local evidence of focal infection. The present complaint is an eruption of the skin extending over the entire anterior surface of the chest, the skin showing very small vesicles rather close together. The skin is boggy and apparently contains fluid in the deeper tissues. The dependent portion of the area is edematous. The skin is sore and itchy, though not reddened. The patient is unable to walk in the upright position because of his desire to keep the clothing from touching the skin. In three days the condition has cleared up in the upper part of the chest but is present over the abdomen, upper part of the thighs, and scrotum. The urine is normal chemically and microscopically.

ROLLIN D. WORDEN, M D, Ravenna, Ohio

*ANSWER*—On the basis of the history given it would seem that a diagnosis should be considered from three special points of view: (1) allergic, (2) parasitic and (3) bacteriologic.

The customary tests for allergy may be helpful in eliminating this possibility. Scrapings from the skin might disclose that the condition is due to an extensive scabies with an accompanying cellulitis, or a staphylococcal infection of the skin might be determined.

Treatment will depend primarily on the cause of the condition, but in any event soft clean muslin underwear should be worn next to the skin. The underwear must be changed daily. The parts involved should be bathed with bran water without the use of soap if the skin is much irritated. Calamine lotion without phenol (carbolic acid) may be useful in relieving the itching. Until a definite diagnosis is established, other essentials for successful treatment cannot be decided on.

#### EFFECTS OF CERVICAL SYMPATHECTOMY

*To the Editor*—What are the late results of cervical sympathectomy? Textbooks and journals to which I have access give no information as to harmful sequelae that may appear, because of the operation, from five to fifteen years after resection of the cervical sympathetic ganglions. Alexander performed bilateral extirpation of the superior cervical sympathetic ganglions in 1889 for epilepsy, and Jaboulay, Jonnesco and Ball did the same operation for other conditions. The operation as employed in the earlier cases was soon discarded but Jonnesco's operation in 1916 for angor pectoris has become a recognized clinical procedure. Sufficient time has now elapsed for reports of harmful late sequelae to appear in the literature if there are any.

E. A. PETERMAN, M D, Detroit

*ANSWER*—A unilateral cervical sympathectomy results in the unilateral Horner's syndrome, which of course is rather unsightly, since the pupil on the operated side is slightly smaller than on the opposite side. The upper lid has a tendency to droop as a result of the section of the sympathetic fibers to the small muscle that is situated between the lid margin and the tarsal plate, the tarsalis muscle. There is an associated dryness of the skin and this is particularly evident when a bilateral cervicothoracic sympathectomy has been performed. The dryness does not result in any skin diseases and is readily protected by natural oils such as the wool fats.

There have been no cerebral disturbances even though the operations have not altered the convulsive procedures.

In a few instances the increased blood supply to the mucosa of the nose and nasopharynx has resulted in a sensation of stuffiness. This phenomenon of increased blood supply has been of a more beneficial than detrimental factor in most instances.

#### CONNECTION OF MUSCLE FIBER AND TENDON

To the Editor:—What is the histologic picture and the manner of connection of muscle fiber and tendon fiber? M.D., New York.

ANSWER.—The exact nature of the connection between muscle fibers and tendon fibers requires further investigation. The sarcolemma that encloses the muscle fibers is closely attached to the white fibers of the tendons, apparently more closely attached to the tendon fibers than to the muscle fibrils themselves. Some authors (Schultze) have shown an apparent continuity in some animals of muscle fibrils across the sarcolemma with the white fibers of tendons. In other animals there is no such continuity and the muscle fibrils are easily detached from the sarcolemma at the end of a muscle fiber. It is possible that the mode of attachment of muscle fibrils to sarcolemma or to tendon fibers differs in different animals.

The connective tissue network made of white fibers and elastic fibers, which surrounds individual muscle fibers, is directly continuous with the similar network that surrounds bundles of white fibers in the tendon, and undoubtedly the greater part of the pull of contracting muscle fibers is transmitted through this continuous connective tissue envelop rather than through the attachment of muscle fibril to sarcolemma and to tendon fibers. See Baldwin: *Morphologisches Jahrbuch* 45:249, 1912.

#### HAZARD OF TETANUS IN SEWING MATTRESSES

To the Editor:—In caring for patients who work in a PWA mattress factory, I have been using tetanus antitoxin in all cases of puncture wounds with a needle. The cotton is unprocessed and I was afraid of tetanus. However, many of the women injure themselves and never report it. So far no case of tetanus has ever developed. Do you feel that it is necessary to use tetanus antitoxin in such cases? Please omit name and address. M.D., Ohio.

ANSWER.—Unless tetanus is present in the community or unless cases of tetanus have been reported from wounds produced in connection with unprocessed cotton, there is no need of giving tetanus antitoxin.

It would be well, however, to sterilize the needles at frequent intervals and to have the workers wash their hands frequently with soap and hot water, in order to minimize the danger of other types of infection.

#### SYMPATHECTOMY IN ANGINA PECTORIS

To the Editor:—Would you kindly let me know for the benefit of a relative the present status of sympathectomy in angina pectoris? Is advanced age a contraindication? M.D., Havana.

ANSWER.—A sympathectomy that includes the superior cervical sympathetic ganglions or the cervicothoracic stellate ganglions is of moderate value in the treatment of angina in younger patients not over 45 years of age, when vasospasm appears to be the predominant feature in the pain complex. Either one of these operations interrupts the fibers carrying the vasomotor impulses to the coronary arteries. The stellate ganglion resection not only interrupts the fibers carrying the vasomotor stimuli but also interrupts some of the fibers carrying afferent pain sensations.

Advanced age definitely contraindicates a sympathectomy, since the cardiac symptoms are probably due more to sclerotic changes than to any vasospasm.

#### STAB WOUND OF PRECORDIUM

To the Editor:—Nov. 15, 1935, a young Negro was stabbed in the precordial region, the wound opening the pericardial sac and penetrating the lung in that region. The heart muscle was exposed quite extensively but the pericardium was not repaired. The chest wound was closed and healed readily but the patient is not recovering his strength. He complains of weakness and lack of appetite, and he is losing weight. I would be glad to have your opinion about this case. Please omit name. M.D., Indiana.

ANSWER.—It is not possible to answer the question on the basis of the data available. It would seem, however, that the symptoms are not due to the results of the wound, if this has healed without infection or complications. The patient should be examined for some other source of infection, and perhaps the postoperative therapy should be critically reviewed. One occasionally overdoes medication in a critical case.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 23-25. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, Sept. 1. Sec., Dr. W. W. Council, Juneau.

ARIZONA: Phoenix, July 7-8. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: *Basic Science*. Little Rock, Nov. 2. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. *Medical (Regular)*. Little Rock, Nov. 10. Sec., Dr. A. S. Buchanan, Prescott. *Medical (Eclectic)*. Little Rock, Nov. 10. Sec., Dr. Clarence H. Young, 207½ Main St., Little Rock.

CALIFORNIA: San Francisco, July 6-9, and Los Angeles, July 20-23. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, July 7. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT: *Medical (Regular)*. Hartford, July 14-15. *Endorsement*. Hartford, July 28. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Medical (Homeopathic)*. Derby, July 14. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: July 14-16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: Washington, July 13-14. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

HAWAII: Honolulu, July 13-16. Sec., Dr. James A. Morgan, 48 Alexander Young Bldg., Honolulu.

IDAHO: Boise, Oct. 6. Commissioner of Law Enforcement, Hon. Emmitt Pfost, 205 State House, Boise.

ILLINOIS: Chicago, June 23-26. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 23-25. Sec., Board of Medical Registration and Examination, Dr. William R. Davidson, Room 5 State House Annex, Indianapolis.

IOWA: *Basic Science*. Des Moines, July 14. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.

MAINE: Augusta, July 7-8. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, July 14-16. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MISSISSIPPI: Jackson, June 22-23. Sec., State Board of Health, Dr. Felix J. Underwood, Jackson.

MONTANA: Helena, Oct. 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

NEW HAMPSHIRE: Concord, Sept. 10-11. Sec., Board of Registration in Medicine, Dr. Charles Duncan, State House, Concord.

NEW MEXICO: Santa Fe, Oct. 12-13. Sec., Dr. Le Grand Ward, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 22-25. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, July 7-10. Sec., Dr. G. M. Williamson, 4½ S. 3d St., Grand Forks.

OREGON: *Basic Science*. Corvallis, July 18. Sec., Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 7-11. Sec., Board of Medical Education and Licensure, Mr. Clarence E. Ackley, 400 Education Bldg., Harrisburg.

PUERTO RICO: San Juan, Sept. 1. Sec., Dr. O. Costa Mandry, Box 536, San Juan.

RHODE ISLAND: Providence, July 2-3. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 23. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Rapid City, July 21-22. Dir., Division of Medical Licensure, Dr. Park B. Jenkins, Pierre.

TEXAS: Austin, June 23-25. Sec., Dr. T. J. Crowe, 918-19-20 Mercantile Bldg., Dallas.

UTAH: Salt Lake City, July 10. Dir., Department of Registration, Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.

VERMONT: Burlington, June 24. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

WASHINGTON: *Basic Science*. Seattle, July 9-10. *Medical*. Seattle, July 13-15. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.

WEST VIRGINIA: Bluefield, July 13. State Health Commissioner, Dr. Arthur E. McClue, Charleston.

WISCONSIN: Milwaukee, June 30-July 3. Sec., Dr. Robert E. Flynn, 401 Main St., La Crosse.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS. *Parts I and II*. June 22-24 and Sept. 14-16. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examination and review of case histories of Group B candidates will be held in various cities in the United States and Canada, Nov. 7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: New York, Sept. 26. All applications and case reports must be filed sixty days before date of examination. Address, 122 So. Michigan Ave., Chicago.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Cleveland, Jan. 9. Sec., Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OPHTHALMOLOGY: New York, Sept. 25-26. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Baltimore and Cincinnati in November. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 29-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Cleveland, Sept. 25-27. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester, Minn.

### Pennsylvania January Examination

Mr. Clarence E. Ackley, secretary, State Board of Medical Education and Licensure, reports the examination given in Philadelphia, Jan. 14-16, 1936. Forty-two candidates were examined, 41 of whom passed and 1 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Georgetown University School of Medicine (1931), (1934, 2)	(1933),	(1933),	4
American Medical Missionary College, Chicago	(1902)		1
State University of Iowa College of Medicine	(1933)		1
University of Maryland School of Medicine and College of Physicians and Surgeons	(1934)		1
Boston University School of Medicine	(1934)		1
University of Minnesota Medical School	(1933)		1
St. Louis University School of Medicine	(1923)		1
Washington University School of Medicine	(1934)		1
Long Island College Hospital	(1906)		1
University of Buffalo School of Medicine	(1933)		1
Hahnemann Medical College and Hospital of Philadelphia	(1934, 3)		3
Jefferson Medical College of Philadelphia (1933, 4),	(1934, 5)		9
Temple University School of Medicine	(1934, 3)		3
Univ. of Pennsylvania School of Medicine (1933, 2),	(1934)		3
University of Pittsburgh School of Medicine	(1934, 2)		2
Woman's Medical College of Pennsylvania	(1933), (1934)		2
University of Virginia Department of Medicine	(1933)		1
University of Wisconsin Medical School	(1933)		1
Dalhousie University Faculty of Medicine	(1932)*		1
McGill University Faculty of Medicine	(1934)		1
Regia Università degli Studi di Roma Facoltà di Medicina e Chirurgia	(1931)†		1
University of St. Andrews Conjoint Medical School, Scotland	(1934)		1

School  
Johns Hopkins University School of Medicine . . . (1913)

Nine physicians were licensed by endorsement from January 6 through January 30. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
University of California Medical School	(1916)	California	
University of Colorado School of Medicine	(1934)	N. B. M. Ex.	
Northwestern University Medical School	(1931)	Illinois	
Johns Hopkins University School of Medicine	(1921)	Maryland	
Harvard University Medical School	(1930)	N. B. M. Ex.	
University of Minnesota Medical School	(1923)	N. B. M. Ex.	
New York University, University and Bellevue Hospital Medical College	(1931)	New York	
Hahnemann Medical College and Hospital of Philadelphia	(1934)	N. B. M. Ex.	
Marquette University School of Medicine	(1919)	Wisconsin

### Maine March Report

Dr. Adam P. Leighton, secretary, Maine Board of Registration of Medicine, reports the written examination held in Portland, March 10-11, 1936. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Ten candidates were examined, all of whom passed. Two physicians were licensed by reciprocity and 2 physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Georgetown University School of Medicine	(1934)		85
Northwestern University Medical School	(1935)		90
Boston University School of Medicine	(1933)		85
Tufts College Medical School	(1935)		85
Creighton University School of Medicine	(1934)		86
University of Vermont College	(1934)		91
McGill University Faculty of Medicine	(1934)		88, 89
Regia Università degli Studi di Medicina e Chirurgia	(1931)		79*

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Harvard University Medical School	(1930)		Ohio
Vanderbilt University School of Medicine	(1930)		Tennessee

School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
Yale University School of Medicine	(1933), (1934)	N. B. M. Ex.	

\* Verification of graduation in process

### Wyoming Reciprocity Report

Dr. G. M. Anderson, secretary, Wyoming State Board of Medical Examiners, reports 4 physicians licensed by reciprocity after an oral examination given in Cheyenne, Feb. 10, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Colorado School of Medicine	(1932)		Colorado
University of Illinois College of Medicine	(1932)		Illinois
State University of Iowa College of Medicine	(1934)		Iowa
University of Tennessee College of Medicine	(1930)		Missouri

## Book Notices

**The National Formulary.** Sixth Edition. National Formulary VI Prepared by the Committee on national formulary, by authority of The American Pharmaceutical Association Official from June 1, 1936. Cloth Price, \$5 Pp 556. Washington, D. C.: American Pharmaceutical Association, 1935.

Concurrent with the appearance of the new U. S. Pharmacopeia, the sixth edition of the National Formulary became available. The revisions of this standard reference work, although less significant than changes in the Pharmacopeia, do have their influence on drug therapy and prescription writing. The 320 items omitted are relatively unimportant, because most of them have long since passed into the realm of unnecessary (but unfortunately still prescribed) drugs. The 239 additions include eighty-three items discarded by the Pharmacopeia. Only twenty of these drugs were included in the later editions of Useful Drugs; only two are to be retained in the forthcoming edition—lime and pilocarpine hydrochloride. Other additions include dosage forms of new Pharmacopeial items, several preparations derived from New and Nonofficial Remedies, and at least one (tetrachloroethylene) from medical literature. It is difficult to understand why some items are continued in the present edition. Elixir of five bromides and the compound elixir of glycerophosphates containing eleven ingredients appear to be entirely superfluous. In accord with the admission to the Pharmacopeia of emulsion of liquid petrolatum, the National Formulary admits emulsion of liquid petrolatum with phenolphthalein. The number of fluidextracts has been greatly reduced, while the ampules and tablets have increased in number. Ampules involve the use of "ampule glass," "ampule water" and "ampule oil," the latter being "any bland fixed oil" controlled (only) as to acidity. Tablets are described according to the percentage content and not their dosage size. Thus, any size tablet may be official (this is true also of the one official U. S. P. tablet). The Formulary describes iso-alcoholic elixir, which is a mixture of a low and a high alcoholic elixir in correct proportions for the ingredients. The new syrup of cherry has been noted to be superior to the older syrup of wild cherry. The oral use of the newly admitted ovary, corpus luteum and anterior pituitary is contrary to practical therapeutics. The make-up of the book is improved, the index extensive, and there has been cooperation on many points with the new Pharmacopeia. It has never been established that a second book of standards is essential to pharmacotherapeutics. Certainly, as far as the physician is concerned, this second official standard is of much less importance than the U. S. Pharmacopeia.

**Experimental Changes in Liver Function: A Contribution to the Diagnosis of Liver Function.** Av Yngve Åkerrén, Med. Lic. av Södermanlands-Nerikes Nation Akademisk avhandling som med tillstånd av medicinska fakulteten i Uppsala för vinnande av medicinsk doktorsgrad till offentlig granskning framställes. Paper. Pp. 287. Uppsala: Almqvist & Wiksells Boktryckeri-A-B, 1934

Åkerrén has carried out an extensive piece of work to see whether, following inanition or the giving of a ketogenic diet, signs of deficient liver function can be elicited with the several tests in common use. The work was done on patients, many of them children, who did not have any sign of liver disease. Åkerrén first studied the amount of urobilin in the urine and found no consistent increase in the patients who were on the ketogenic regimen. There was only one person who showed an excessive urobilinuria when following this regimen or when fasting. The administration of sodium bicarbonate or of a mixture of citric acid and sodium citrate in doses of from 15 to 29 Gm. in the twenty-four hours caused a definite increase in the amount of urobilin in the urine. Åkerrén next studied the influence of a ketogenic diet on the assimilation of galactose. Here he found a definite decrease in the ability of the patients to handle the sugar. Not only did more galactose appear in the urine but there was an increase in the blood sugar. If enough carbohydrate was added to the protein and fat to prevent ketonuria, there was no abnormality in the handling of the galactose. Similar observations were made with levulose. Either the ketogenic diet or fasting commonly gave rise to a positive Hay's test, which appears to be an exceedingly delicate

test for the presence of bile acids in the urine. The ketogenic diet did not produce an increase of bilirubin in the serum. Åkerrén believes that the lessened ability of the body to assimilate galactose following the use of a ketogenic diet is due to injury to the liver, and he thinks that this may well be due to a decrease in the glycogen content of this organ and to an increased formation of ketone bodies there. He believes also that, in some cases of jaundice produced mechanically, the glycogen content of the liver is probably lessened and as a result the assimilation of galactose is interfered with. Åkerrén believes that the changes in the blood sugar which he observed are due to injury to the liver. Many of his arguments are based on a review of the literature.

This monograph should be of considerable interest to every one who is studying liver function. As the author points out, there still is much to learn about the rationale of the tests used for the estimation of liver function; thus far most of them have been used only empirically. Åkerrén is most appreciative of the work of Mann and Bollman on animals, but, as he says, it is one thing to remove six sevenths of a dog's liver and to test the function of the remaining seventh with its perfectly normal cells, and it is another thing to test in man the function of a full sized liver with perhaps every one of its cells slightly damaged or inhibited in some way.

**The Tuberculin Handbook.** By Halliday Sutherland, M.D., Honorary Physician to the Queen Alexandra Sanatorium Fund, London. Cloth. Price, \$2.75. Pp. 96, with 14 illustrations. New York & London: Oxford University Press, 1936.

Sutherland states in the preface that he believes that, apart from the discovery of the tubercle bacillus, tuberculin in the diagnosis and treatment of tuberculosis is Koch's greatest gift to mankind. The chapter on the discovery of tuberculin deals with the early work of Koch and the preparation of various kinds of tuberculin that have been used from time to time. The Use of Tuberculin is a summary of the symptoms, signs and x-ray appearances of the disease in early pulmonary tuberculosis. He cites cases to show the impossibility of making diagnoses by x-ray films without the use of tuberculin, for "by means of the tuberculin tests pulmonary tuberculosis can be distinguished from all other diseases of the lung, and what is of greater value to the patient and to the community the disease can be diagnosed in its earliest stages long before tubercle bacilli have appeared in the sputum." He further states that none of the early symptoms, physical signs or x-ray appearances are in themselves either singly or combined diagnostic of pulmonary tuberculosis and that the key to their interpretation is in the tuberculin test. The cutaneous tests, such as those of Pirquet and Moro, are presented. Here attention is called to the work of Bernard and others, who separated 171 infants with positive reactions from their tuberculous parents. Over a period of four years of subsequent observation, 7.5 per cent died of tuberculosis, whereas, of sixty-six infants who were left with their tuberculous parents, 82 per cent died during the next four years. Sutherland concludes that the contacts of every case of pulmonary tuberculosis should be tested with tuberculin and that all children found to be infected should be immunized with BCG or with tuberculin. Many physicians will wholly disagree with such a conclusion, since BCG sensitizes the tissues to tuberculinoprotein, since some excellent bacteriologists have shown that it is capable of regaining its virulence, and since almost nothing is known about its possible remote dangers. Many will agree that the use of tuberculin may be of value to desensitize such children but will question whether it has any immunizing effect. Attention is also called to the fact that for a long time it has been known that certain individuals react negatively to the tuberculin test, although tuberculosis is present. However, the number apparently is not large and the explanation of the discrepancy usually is easy. The intracutaneous test of Mantoux is discussed at some length, with a careful description of the technic of administration, preparation of dilutions, and interpretation of reactions. Sutherland looks on this as the most accurate of all the cutaneous tests. However, he is not entirely in sympathy with the substitution of purified protein derivative for old tuberculin. A good many workers will disagree with recommendations concerning the subcutaneous test, as well as statements concerning

tuberculin treatment, except when tuberculin is used to desensitize the tissues. This book presents much valuable information regarding the use of tuberculin and is worthy of careful reading by every physician.

**Thérapeutique médicale, IX: Maladies infectieuses et parasitaires.** Par M. Loeper, avec la collaboration de R. Turpin et al. Paper. Price, 50 francs. Pp. 415. Paris: Masson & Cie, 1935.

The first part of this ninth and last volume of *Thérapeutique médicale* deals with general therapeutics. It includes chapters on vaccination, serotherapy, bacteriotherapy, chemotherapy, protein therapy and hemotherapy. The second part, special therapeutics, contains articles on disinfection (L. Tanon), treatment of dysenteries (M. Dopter), prevention and cure of tetanus (L. Bazy), treatment and prevention of influenza—"la grippe"—(R. Dujarric de la Rivière), general principles of treatment of malaria (P. Abrami), bismuth treatment and bismuth prevention of syphilis (C. Levaditi), antityphoid vaccination (A. Lemierre), inoculation against diphtheria with Ramon's antitoxin (R. Debré), vaccine therapy against diseases caused by filtrable viruses (A. Pettit), convalescent serums (P. Joannon), and treatment with vitamins in infectious diseases (E. Lesné). The book does not give a systematic discussion of the treatment of infectious diseases but presents a series of articles on selected topics with special reference to serums, vaccines and chemotherapy. Some of the articles are rather fragmentary. The only article provided with references to the literature is that by Levaditi on bismuth in the cure as well as prevention of syphilis. As a rule the tendency of the articles is conservative. The oral ingestion of antityphoid vaccine is held to be of such doubtful value that it is not recommended for practical use. In the article on prevention of diphtheria, no mention is made of the one dose method with alum precipitated diphtheria toxoid. The book does not contain any account of the treatment of scarlet fever with specific antitoxic serum or of its prevention by the injection of susceptible persons with the toxin of the scarlet fever streptococcus. There is no index—only a short general table of contents.

**A Textbook of Obstetrics for Students and Practitioners.** By Frederick C. Irving, A.B., M.D., F.A.C.S., William Lambert Richardson Professor of Obstetrics, Harvard University Medical School. Cloth. Price, \$6. Pp. 558, with 357 illustrations. New York: Macmillan Company, 1936.

This is an extensive elaboration of outlines used in the teaching of students in the Harvard Medical School. The author purposely avoided making the book embrace the entire field of obstetrics. All the illustrations except the reproductions of roentgenograms are simple drawings. Many have been reproduced from other textbooks. All except the roentgenograms are clear and instructive. The book is divided into the conventional chapters. The analgesic which the author prefers is pentobarbital in combination with scopolamine. In the discussion of postpartum care the impression is given that the examinations made six weeks post partum is the final contact between the physician and an obstetric patient. This is unfortunate, because women who have given birth should not be discharged when the baby is 6 or 8 weeks of age but should be seen at least twice more during the first year following confinement and if possible once a year thereafter. Septic abortion is treated conservatively at the Boston Lying-in Hospital, just as it is in most large clinics in this country. In the treatment of placenta praevia a low maternal mortality has been secured by conservative means; but, because the fetal death rate has been high, the author has decided to be more liberal in his indications for cesarean section provided the risk to the mother is not thereby increased. In some large clinics, such as those of De Lee and Bill, large series of cesarean sections have been performed for placenta praevia with low maternal and relatively low fetal death rates. Irving also favors conservatism in the treatment of premature separation of the placenta. He divides the toxemias of late pregnancy into preeclampsia and eclampsia and advocates conservative therapy for both conditions. At the Boston Lying-in Hospital, three types of cesarean section are performed: the classic, the lower segment and the extraperitoneal. The death rate from all causes among 1,025 such operations was 3.7 per cent. The book is well written and is based chiefly on the author's extensive experience as an obstetrician and teacher. Students and practitioners should find this book helpful.

**Gynecology for Students and Practitioners.** By T. Watts Eden, M.D., C.M., F.R.C.P., Consulting Gynecologist, Charing Cross Hospital and Chelsea Hospital for Women, and Cuthbert Lockyer, M.D., B.S., F.R.C.P., Consulting Gynecologist, Charing Cross Hospital. Fourth edition. By H. Beckwith Whitehouse, M.B., M.S., Ch.M., Professor of Midwifery and Diseases of Women, University of Birmingham. Cloth. Pp. 964, with 655 illustrations. London: J. & A. Churchill, Ltd., 1935.

This heavy book of nearly a thousand pages is the fourth revision of gynecology originally written by Eden and Lockyer. It is now edited for the first time by H. Beckwith Whitehouse, who has brought it down to date not only by revision but also by rewriting several sections of the work, with the addition of considerable new material. This, and the profusion of illustrations, account for the size of the volume. The book is truly encyclopedic in its scope, being somewhat too complete, in fact, to be altogether readable. Some of its chapters are quite brisk in their style, however, and as a reference work it is admirable. Plates in color, half-tone drawings in black and white, line drawings by pen and ink, retouched photographs, and photomicrographs follow one another in such generous profusion that only a few pages lack one or the other in elaboration of the text. Many of these illustrations are excellent, but others are disappointing because they are apparently so old. The newer additions are by far the most satisfactory. The book is written and arranged in a style to which American readers are not entirely accustomed. The thoroughness with which the subject of gynecology is covered is characteristically British, although it is perhaps slightly bewildering to us in its meticulousness of detail. Whitehouse has added a timely section on the physiology of the female sex organs which is a companion to his chapters on functional disturbances and sterility. He has entirely rearranged the subject matter of the earlier editions by deliberately omitting as much as possible of symptoms and physical diagnostic signs from those portions of the book wherein he deals with etiology, clinical pathology, and the general nature of various gynecologic disorders. Then, toward the end of the book he groups and presents, rather uniquely, these previously deleted facts in an excellent section on gynecologic diagnosis and treatment. This is followed closely and logically by one on operative technic and another on post-operative treatment. Its having been edited and rewritten by a single authority has made possible the avoidance of the all too common faults of duplication and repetition. Its size is due solely to its being so comprehensive. The very completeness of this work recommends it as valuable to the library of the student, practitioner or specialist in gynecology.

**Modern Ophthalmic Lenses and Optical Glass.** By Theo. E. Obrig, A.B., Secretary, Gall & Lemke, Inc. Cloth. Price, \$4.50. Pp. 323, with 168 illustrations. New York: The Author, 1935.

In the preface to this valuable little treatise the author says that "an effort has been made to present the subject matter in as simple and concise a manner as possible." He has succeeded admirably in fulfilling his task. The history and an acquaintance with the story of optical glass and eye glasses should be of interest not only to the ophthalmologist and his helper the optician but indeed to every lay person, for each must be aware of the fact that, around the age of 45 or before, spectacles are a necessity in counteracting the loss of accommodation which nature imposes on all human beings. The enormous amount of effort and expense consumed in bringing the crude sand to form a scientifically perfect lens is stressed by the author, thus giving a real insight into the whys and wherefores of the necessity for exactness and the cost of the finished product. The difficulty with becoming accustomed to the bifocal lens is thoroughly discussed, and each of the many types now in use has its advantages and disadvantages well presented. Those modern ocular instruments which have been evolved to aid persons with poor sight, such as the contact lenses, the telescopic spectacles and the isekonic lenses to equalize the visual images of the two eyes, are considered in a manner most commendable. By directing attention to the protective lenses of color and those nonshatterable, the worker in hazardous occupations is apprised of the means at hand to prevent injury to the eye, which stands first in the list of causes of blindness. So too the worker in special fields in which it is desirable to have various focal distances because of the nature of the labor has demonstrated to him the value and defects of multifocal

lenses. The means at hand to include prismatic effects in eye glasses to compensate for ocular muscle difficulties and thus overcome double vision, vertigo, dizziness and the like is set forth in a masterful manner. Proper emphasis of the adjustment of the properly made lens in its relation to its position with regard to the eye is elucidated. If any derogatory criticism is indicated, it is a fault in the illustrations, the figures in many being so small and indistinct as to be illegible. The "desire to present a short reference book which gives the elementary facts we should all know, about the history of glass, the manufacture of glass, colored lenses and the reasons for their need" has been carried out by the author in a thorough and simple manner.

**Recent Advances in Cardiology.** By Terence East, M.A., D.M., F.R.C.P., Physician, King's College Hospital, London, and Curtis Bain, M.C., D.M., M.R.C.P., Physician, Harrogate General Hospital. Third edition. Cloth. Price, \$5. Pp. 350, with 99 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1936.

The first edition of this work appeared in 1929. In a sense the title is a misnomer. The volume is really a small textbook on cardiology largely made up of material so old that it cannot be classed as recent. This was also true of the second edition of 1931. The authors have, however, included a judicious selection from the newer facts concerning heart disease and in so doing have really rewritten the book. Two new chapters have been added, one on vascular diseases and one on congenital defects. The book can be recommended as a reliable, though by no means complete, work on disease of the heart, useful for the student who may be cramming for an examination or for the busy practitioner who wishes to brush up with a bird's-eye view of the subject. It is not, however, a work of reference or of study for one desiring thorough knowledge or who aims to qualify as a specialist in this field of practice.

**Blutkörperchensenkung.** Von Dr. Hans Relchel, Facharzt für innere Medizin, I. Med. Klinik in Wien. Unter Mitarbeit von Dr. P. Fasal et al. Paper. Price, 18 marks. Pp. 261, with 30 illustrations. Vienna: Julius Springer, 1936.

This textbook emanates from the First Medical Clinic of Vienna. It gives a complete story of the nonspecific test known as the blood sedimentation test. It shows the application of this test in diagnosis, prognosis and treatment. This is a complete account of the literature that has appeared in the last sixteen years. In addition, the author gives his experiences and conclusions based on a study of about 8,000 patients in the First Medical Clinic of Vienna, 3,000 of whom have been studied in the past year and a half. The technic of the method is completely set forth, together with its theory and physiology, and its bearing on general and experimental pathology, internal medicine, pediatrics, surgery, gynecology and obstetrics, skin, the sexual organs, the nervous system, ocular appearance, nose, throat and ear, as well as a special chapter on veterinary medicine, all of which tells the complete story of just how useful blood sedimentation is in medical practice. The author deserves great credit for assembling this literature and for having so painstakingly given his point of view based on an enormous personal experience. It is a valuable book for reference.

**A Textbook of Roentgenology: The Roentgen Ray in Diagnosis and Treatment.** By Bede J. Michael Harrison, M.B., Ch.M., D.M.R.E., Director of Department of Roentgenology, Vancouver General Hospital. Cloth. Price, \$10. Pp. 826, with 238 illustrations. Baltimore: William Wood & Company, 1936.

In the introductory chapter the author announces that this book is addressed not to roentgenologists but to general clinicians and is intended primarily to enable the practitioner to understand the basis on which roentgenology rests, so that he may better comprehend its applications and limitations. To this end the author has striven to correlate morbid anatomy with roentgenology. Hence in the discussion of individual diseases the pathology is described first, and this is followed by a summary of the roentgenologic manifestations and the therapeutic effects of irradiation. Because the author's purpose, to which he has applied himself with obvious enthusiasm, is praiseworthy, and because clinicians can scarcely fail to profit from reading the volume, it is with reluctance that any adverse criticisms are offered. The chapters on the nature of roentgen evidence, on inflammation and on infection are excellent, but,

although the morbid anatomy of individual diseases is set forth with meticulous detail, the link with the roentgenologic phenomena is too often not pointed out specifically. Illustrative roentgenograms with analytic explanatory legends would have helped to show the link, but the number of illustrations is insufficient, legends are terse, and many common disorders are not illustrated at all. Especially regrettable are the incautious statements concerning the effectiveness of radiotherapy for certain disorders, such as gallstone colic, malfunctioning gastroenterostomy, traumatic epilepsy, and feeble-mindedness in children, for few experienced radiologists would recommend irradiation for these conditions. Similarly, in some instances the criteria of diagnosis include items that are of doubtful validity. In short, the book seems to be a compilation of material drawn from many sources without the judicious discrimination that follows wide experience.

*Études expérimentales récentes sur les maladies infectieuses.* Par Jean Troisier, professeur agrégé de pathologie expérimentale et comparée à la Faculté de médecine de Paris. Paper. Price, 45 francs. Pp. 279, with 50 illustrations. Paris: Masson & Cie, 1935.

In the first part of this book the following diseases are grouped together because they appear to be caused by specific agents of as yet undetermined nature: fowl sarcoma (Rous), inguinal lymphogranuloma (in French *maladie de Nicolas-Favre*, lymphogranulomatosse bénigne), yellow fever, influenza and coryza ("common cold"), vaccinal encephalitis and common jaundice (l'ictère commun). The second part includes spirochetosis *icterohaemorrhagica* and its meningeal variant, apparently a new nosologic entity first recognized and described by the author of this book and his associates (Troisier, Jean, and Boquien, Yves: *La spirochetose méningée*, Paris, Masson et Cie, 1933, reviewed in *THE JOURNAL* Sept. 2, 1933, p. 803), visceral leishmaniosis, and la fièvre buttonneuse, a typhus-like disease so far found mainly in the Mediterranean basin and caused by a form of *Rickettsia*. The third part takes up typhoid and paratyphoid fevers, tularemia, swine erysipelas, brucellosis of bovine origin, tetanus, and gas bacillus (*Clostridium Welchii*) septicemia (in French *septicémie à Bacillus perfringens*). The next part reviews leprosy and certain forms of tuberculosis. The relations of human to rat leprosy are discussed in detail. The forms of tuberculosis considered are tuberculous infection by way of cutaneous inoculation and the septicemic form known in French as *la typho-bacilliose*. The two remaining parts deal briefly with agranulocytosis and with "virus néphrotropes"—infectious agents of various kinds that have a special affinity for renal tissue. The illustrations are good. The style is clear and concise. Many authors are cited in the text without any reference being given to their publications. Of misspelled names may be noted Brill for Bull, Huddlesen for Huddleson, MacCoy for McCoy and Wallgreen for Wallgren. As usual in French books of this general type, there is no index—only a table of contents.

*Twentieth Century Psychiatry: Its Contribution to Man's Knowledge of Himself.* By William A. White, M.D., A.M., Sc.D. Cloth. Price, \$2. Pp. 198. New York: W. W. Norton & Company, Inc., 1936.

This is the second Thomas W. Salmon memorial lecture to be published. It is divided into an introduction and three chapters on psychiatry as a medical specialty, the social significance of psychiatry and the general implications of psychiatric thought. In the introduction the author discusses and describes the history of psychiatry from the time of Pinel. He feels that practically all the changes in our ideas regarding psychiatry have occurred in the last fifty years. In the first chapter he discusses psychoanalysis and mental hygiene. He pleads for more research and constructive criticism for psychoanalysis. In the second chapter he discusses the social aspect and significance of mental disease in relation to federal and state budgets, relations of the individual to his community, and the social significance of his conduct and mental disorder. In the third chapter he emphasizes the tremendous growth of science during the present century and the extent to which psychiatric thinking has developed and become amalgamated with the advances in thought in all directions which directly or indirectly affect man and his activities. This is a popular publication and is recommended to all neuropsychiatrists. The author mentions about twenty-five books and publications used for references.

*Principles and Practice of Preventive Medicine.* Edited by C. W. Hutt, M.A., M.D., M.R.C.P., and H. Hyslop Thomson, M.D., D.P.H., Medical Officer of Health for the County of Hertford. In two volumes. Cloth. Price, £3 13s. 6d. Pp. 1,638, with 215 illustrations. London: Methuen & Co., Ltd., 1935.

In presenting these volumes Dr. Thomson calls attention to the untimely death of Dr. C. W. Hutt, who died while the book was going through the press. The two volumes constitute a system of preventive medicine to which many leading authorities of Great Britain have contributed. The first volume is concerned with prevention of infectious, the control of insects and vermin, and the hygienic problems involved in the control of food and water supplies. It concludes with a chapter on the disposal of the dead. The second volume proceeds to consider such topics as air, climate, housing, ventilation, lighting, smoking, maternal and infant welfare, industrial medicine, the hygiene of aviation, popular education in health, and many other modern topics. Although the books are peculiarly British in their approach to the subjects concerned, they advance many interesting suggestions for American and other readers. There is an extensive index which makes easy consultation of this valuable reference work on many hundreds of topics. The scope of the work is an indication of the tremendous advance that has taken place in preventive medicine during the past fifty years. The publishers have done a magnificent job of printing, using a thin enameled stock which lends itself beautifully to illustration and which permits a great number of pages of information in a small bulk. It is not possible in the scope of a review such as this to consider item by item the great field covered. The repute of the editors and of the individual authors is sufficient indication of the reliability of the material.

*The Mayo Clinic.* By Lucy Wilder. Cloth. Pp. 82, with illustrations by Ruth Barney. Rochester, Minnesota: The Author, 1936.

This volume is obviously published *con amore* about the origin, growth, development and present status of the Mayo Clinic. The book is the work of Lucy Wilder, wife of Dr. Russell M. Wilder. It is artistically designed with drawings and maps, artistically developed pages with inset sketches, and for any one who has been to the Mayo Clinic or who wishes to know in brief about it a useful book as well as a pleasing memento. The story of the Mayo Clinic is given in three chapters entitled "The Past," "The Future" and "The Present," and the volume concludes with the letter from Dr. William J. Mayo to the University of Minnesota establishing the Foundation—a document which is already historically epoch making because of its purpose and its statement of the aims of wealth.

*Proceedings of the National Conference of Social Work [Formerly National Conference of Charities and Correction] at the Sixty-Second Annual Session Held in Montreal, Canada, June 9-15, 1935.* Cloth. Price, \$3. Pp. 748. Chicago: The University of Chicago Press, 1935.

The papers presented at this conference show an almost complete transformation in social work and its treatment during recent years. The discussion of broad social problems now takes a prominent place. Even the technical discussions center around recent legislation, such as the Social Security Act and emergency relief measures. Much attention is given to "group work" and its relation to problems of social change. H. M. Cassidy, director of social welfare for British Columbia, describes the newly adopted system of health insurance in British Columbia. In the papers dealing with medical social work the necessity of medical leadership is stressed, something often overlooked in carrying out recent health programs.

*Elementary Bacteriology.* By Joseph E. Greaves, M.S., Ph.D., Professor of Bacteriology, Utah Agricultural College, Logan, and Ethelyn O. Greaves, M.S., Ph.D. Third edition. Cloth. Price, \$3.50. Pp. 562, with 147 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

This was written to furnish a suitable textbook for courses in elementary bacteriology. The hope that it might also prove of interest to nurses, home demonstrators, agricultural and home economic workers and to an ever increasing multitude of readers who are turning from fiction to facts was also expressed. It is simply and entertainingly written. At times the intention of writing simply and entertainingly has led to a somewhat careless method of expression, such as the reference to "T. B." in the introduction. The book would scarcely serve as a text-

book for medical students, but most of it could be read easily by intelligent persons without special scientific training. It might also serve as a useful addition to other textbooks in college courses of general bacteriology. The index is not complete, especially with regard to the authors referred to in the text. It would be helpful in later editions to improve this index. The chapters on milk and milk products, the nitrogen cycle and the carbon cycle are especially interesting. The classification of bacteria is rather too complicated for the rest of the book and its probable readers.

*Kolloid-Fibel für Mediziner.* Von Dr. Dr. Raphael Ed Llesegang, Institut für Physikalische Grundlagen der Medizin, Frankfurt a. M. Paper. Price, 1 mark. Pp. 34. Dresden & Leipzig: Theodor Steinkopff, 1936.

This "Colloid Primer" by one of the foremost authorities on colloids, shows that it takes a master to present a complex subject simply. He chiefly intends this "primer" as a stimulus to the reading of more extensive books. While the reading of this book can be chiefly recommended to one to whom this field is new, its perusal will pay the teacher, as it will enrich his vocabulary with helpful metaphors and similes. "Protective colloid" is "likened to a defensive armor." Soap acts by "one end of its long molecule projecting into the oil (the disperse phase) and the other end sticking out into the water." Each cell is "a mosaic of somewhat more acid and mere alkaline places" and its "membrane, a mosaic of lipoids and of water swelled protein, so that it is permeable to both."

## Miscellany

### OXYGEN ADMINISTRATION

The Committee on Public Health Relations of the New York Academy of Medicine was requested to prepare a memorandum with information concerning the administration of oxygen. The need for this, according to the request, arose from the fact that there are on the market oxygen tents which are not only inadequate but may be a source of actual danger to the patient.

Evidence has come to hand which indicates that oxygen therapy is frequently administered in a wasteful and ineffective manner not only in private practice but also in the wards of hospitals.

#### REGULATION OF OXYGEN CONCENTRATION

The purpose of oxygen therapy is to overcome oxygen want due to some interference with proper oxygenation of the blood, as in pneumonia, coronary thrombosis, congestive heart failure, emphysema or atelectasis. In the presence of fever the metabolism is increased and the oxygen want is thereby increased. If the patient is to be benefited, the amount and concentration of the oxygen employed must be sufficient to compensate for the impairment in the oxygen exchange. It is important that the physician prescribe definitely the concentration of oxygen to be breathed by the patient, just as he prescribes the dose of drugs. The optimum range of oxygen concentration will vary in different patients. In some cases 30 per cent will be adequate to correct the deficiency; in other instances as high as 70 per cent may be required. Continuous use of pure oxygen is harmful, but for periods not exceeding eight hours of the twenty-four a concentration as high as 90 per cent has been found safe. In many cases from 45 to 50 per cent is the most desirable concentration.

A 35 per cent concentration of oxygen in the alveolar air may be achieved by means of a forked nasal tube inhaler or a simple nasal catheter and an oxygen flow of 5 liters per minute. By increasing the flow, even higher concentrations may be obtained. The administration of concentrations between 50 and 70 per cent is in most instances more satisfactorily obtained by the employment of an oxygen tent. The tent also permits air conditioning.

#### TESTING THE OXYGEN TENT PERIODICALLY

If the tent is to fulfil its purpose, it must be able to maintain the desired oxygen concentration. The possibility of leaks developing in the unit is so great that no tent should ever be used unless its oxygen content is tested at least two to three

times a day and the results of the test recorded. The testing is so simple and yet so essential that no physician should ever employ a tent in his private or hospital practice unless provision is made for periodic testing of the oxygen concentration. This test should not be made immediately after the tent has been filled with oxygen. If the circulation is directly through the ice it takes an hour for the concentration of oxygen to be restored to its former height, unless after the icebox is opened the flow rate of oxygen is increased temporarily. The blower should be stopped when ice is added or inspected.

#### OXYGEN TENT THERAPY FOR ADULTS

In addition, three other important conditions must be met. 1. For adults a tent should have a capacity of at least 8 cubic feet. 2. The temperature inside the tent should be maintainable at the desired temperature by means of a cooling device. In most patients with fever a temperature between 58 and 68 F. is preferred in winter and a slightly higher temperature in summer. Higher temperatures are often desirable for older people and infants. 3. The relative humidity should be maintained between 40 and 60 per cent. When tents are ventilated by a motor blower circulation which passes the air over a cooling medium such as ice, the humidity will usually be within this range. If the temperature and humidity are not maintained at these comfort levels, the patient will be distressed and the tent will do much more harm than good. The nurse should be instructed to observe and record the temperature within the tent throughout the day and night, or the temperature and humidity may be recorded by an automatic recording device. If the temperature goes above 70 F. it generally indicates that there is inadequate cooling and frequently inadequate removal of moisture. This may be due to inadequate circulation of air or inadequate provision for cooling.

The carbon dioxide content should not be more than 1.2 per cent. If a minimum flow of 8 liters of oxygen per minute and an oxygen concentration of 50 per cent are maintained, harmful accumulations of carbon dioxide within the tent will not take place even in the absence of soda lime. If lesser rates of oxygen flow and higher concentrations of oxygen are maintained especially for adults with fever, soda lime should be used. Because there is no valid indication for continuous stimulation of the respiratory center, mixtures of carbon dioxide and oxygen are not required for most illnesses. For short periods, such stimulation may be of value in such conditions as carbon monoxide poisoning, drowning, electrical shock, atelectasis of the newborn, and when there is shallow breathing.

Tents which are not equipped with a satisfactory method for cooling and drying the air may be detrimental to the patient and may cause death by heat stroke. No closed canopy should be put over a patient's head unless it is equipped with a cooling and dehumidifying apparatus. Tents without blowers are unsatisfactory in certain climatic regions.

#### OXYGEN TENT THERAPY FOR INFANTS

The same general principles apply to tents for infants, except that higher temperatures, and in some instances higher humidities, should be prescribed for very small infants. Smaller tents may be used. It is dangerous to deprive infants of heat by rapidly circulating cool air over them. A tent with an aperture at the top, and to which the oxygen is admitted at the base, may be used provided it is not placed near an open window or door where air currents may draw out the accumulated oxygen. The oxygen concentration should be tested and recorded. An umbrella or canopy tent without an air conditioner may be used for infants under 2 months of age, since such infants produce insufficient heat, water or carbon dioxide to permit harmful accumulation of these metabolites.

#### STERILIZATION OF THE TENTS

All tents should be sterilized after each use by scrubbing inside as well as outside with soap and water. The tents should therefore be made of double-faced material. After scrubbing, the tent should be dipped in a solution of 1:10,000 mercury bichloride for five minutes. To prevent incrustation, the tent should be washed down with water after immersion in the mercury bichloride. In hospital practice an alternate method would be the dipping of the tent in a 70 per cent solution of ethyl alcohol for five minutes.

## FIRE HAZARDS

1. All tents should be conspicuously stamped "No Flames, No Sparks, Danger."
2. Oxygen gages should be conspicuously labeled "Danger, Do Not Oil."
3. For the window of the tent, only cellulose acetate or other noninflammable material may be employed. Cellulose nitrate or celluloid should never be used because they are extremely inflammable and form dangerous fumes.

## NASAL CATHETER OR NASAL TUBE ADMINISTRATION

There are several effective methods of administering oxygen through the nose, employing a nasal catheter or nasal tube inhaler with a calibrated gage to fit on a high pressure tank. The oxygen must be passed through at least 3 inches of water to prevent drying the mucous membrane.

1. A metal nasal tube inhaler with soft rubber tips that just enter each nostril may be employed.

2. A nasal catheter may be inserted into the nostril for a distance of approximately 3 inches; i. e., up to but not touching the posterior wall of the nasopharynx. Five liters of oxygen generally provides 35 per cent oxygen in the inspired air. A single catheter may be changed from one nostril to the other if irritation should occur. With a double nasal catheter a slightly increased oxygen concentration is obtained at the same rate of flow. The terminal one inch of the catheter should be perforated with four holes in order to prevent a stream of oxygen impinging on one localized area of mucous membrane. The size of the catheter may be a No. 12 French or a somewhat larger caliber if it does not occlude the nasal passage completely.

3. The catheter may be employed in the oropharynx opposite the uvula. When it is used in this position, caution must be exercised lest oxygen be passed into the stomach. The catheter should not be placed lower than the uvula. The throat should be sprayed every eight to twelve hours to prevent drying.

Whereas 4 or 5 liters per minute of oxygen is generally used with the nasal catheter or nasal tube inhaler, higher rates of flow up to 12 liters per minute may be employed if no sensation of discomfort is produced. With the higher rates of flow, larger catheters are required. When catheters are employed it is important to make additional holes in the terminal one inch.

## OXYGEN REGULATOR AND GAGE

Oxygen should be employed in high pressure tanks containing 220 cubic feet, or 6,000 liters. There is only one kind of oxygen, industrial oxygen. There is no special "medical" oxygen.

The flow regulator should have two gages, one to indicate the amount of oxygen in the cylinder, and the other to indicate the rate of flow in liters per minute. A variable orifice or float gage indicates the amount of oxygen actually flowing and is accordingly to be preferred to a dial gage which records the pressure against a fixed orifice as liters per minute. The latter type does not indicate that the oxygen flow may have stopped or has been diminished. Bourdon tube type gages, as well as the pitot tube type gages, should be tested from time to time by measuring the rate at which the spirometer of a metabolism apparatus is filled at standard pressure and temperature.

## CONCLUSIONS

This statement emphasizes:

1. The effectiveness of the nasal inhaler or nasal catheter.
2. The value of a tent for administering high concentrations of oxygen.
3. The desirability of prescription by the physician of the concentration of oxygen in the oxygen tent.
4. The necessity for repeatedly testing and recording the oxygen concentration within the tent.
5. The necessity for observing the temperature and humidity constantly while the tent is in use.
6. The danger to life involved in employing a tent in which an optimum oxygen concentration is not maintained and in which the temperature and humidity are not observed and controlled.

April 6, 1936.

## Bureau of Legal Medicine and Legislation

## MEDICOLEGAL ABSTRACTS

**Chiropractic: Injections for Cancer Illegal; Scope of Chiropractic in California.**—Hartman, a licensed chiropractor in California, was convicted in the justice's court of San Bernardino township, on a complaint charging him with, among other things, (1) the unlawful possession of a hypodermic syringe and needle in violation of sec. 8 (e) of the poison act,<sup>1</sup> and (2) a violation of the medical practice act by practicing medicine without a license. The case was submitted on an agreed statement of facts. Thereafter Hartman appealed to the superior court which affirmed the judgment of conviction, and Hartman made application for a writ of habeas corpus to the district court of appeal, fourth district, California.

In the agreed statement of facts, Hartman admitted that he had in his possession a hypodermic syringe and that he treated cancer "according to the 'Koch' method, by injection of a fluid called 'antitoxin' or split-protein." It was agreed that this method of treating cancer was taught in chiropractic schools and colleges in the state. Hartman contended that his method of practice was authorized by sec. 7 of the chiropractic act of California, which authorizes a licentiate—

to practice chiropractic in the state of California as taught in chiropractic schools or colleges; and, also, to use all necessary mechanical, and hygienic and sanitary measures incident to the care of the body, but shall not authorize the practice of medicine, surgery, osteopathy, dentistry, or optometry, nor the use of any drug or medicine now or hereafter included in materia medica.

The contention was that since the use of the hypodermic syringe and needle and the diagnosis and treatment of cancer by the use of an injection of "antitoxin" were taught in chiropractic schools in California, Hartman was practicing within lawful limits. He further sought to justify the use of the hypodermic syringe by contending that it was merely a measure "incident to the care of the body." The use of the hypodermic syringe, said the district court, cannot be held to be merely a measure "incident to the care of the body," within the meaning of the chiropractic act, because the phrase "incident to the care of the body" refers to general hygienic and sanitary measures, even though mechanical, and not to the treatment of diseases and ailments, and because of the limitations imposed that licentiates shall not be authorized to practice medicine or surgery. The section dealing with the authorized scope of chiropractic must be read as a whole. It cannot be construed as authorizing a licentiate to do anything and everything that might be taught in a chiropractic school. A short course in surgery, or one in law, might be given, but it would not follow that a licensed chiropractor might engage in such other professions. It is not sufficient that a particular practice be taught in a chiropractic school; the practice must constitute a part of chiropractic and must not violate the provision expressly forbidding licentiates from practicing medicine. If a particular practice is not a part of chiropractic, but does constitute the practice of medicine, a chiropractic licentiate may not engage therein, even though it may be taught in a chiropractic school.

The court was unable, however, to determine from the agreed statement of facts whether the method of treatment here in question was or was not a part of the practice of chiropractic. The failure of the petitioner, Hartman, to include in the record that was before the district court all the evidence made it impossible for that court to pass on the sufficiency of it. Furthermore, the rule is well established that the sufficiency of the evidence may not be reviewed in a habeas corpus proceeding. Even if we could properly review the evidence, the court said, there was none in the record which would support a finding that the use of a hypodermic needle or the injection of an "antitoxin" is a part of chiropractic, and no evidence

1. This section provides, in part, that it shall be unlawful for any person other than a physician and surgeon, dentist, registered nurse, veterinarian, or pharmacist licensed to practice in California to have in his possession a hypodermic syringe unless it was purchased on a written order signed by a duly licensed physician, dentist, or veterinarian or by a person holding an unrevoked license to practice osteopathy.

that such forms of treatment do not constitute the practice of medicine. The court held, therefore, that the petitioner was not entitled to be released from custody. *In re Hartman (Calif)*, 51 P (2d) 1104

**Malpractice: Chiropractor's Malpractice Provable Without Expert Testimony.**—The plaintiff consulted the defendant, a chiropractor, relative to pains in her face. The defendant diagnosed her condition as "tic douloureux, inflammation of the fifth cranial nerve." Although this nerve is in no way connected with any portion of the vertebrae, the chiropractor, during the course of treatment of the patient's ailment, fractured her twelfth rib while adjusting her vertebrae in that region. The patient sued the chiropractor, and the trial court, sitting without a jury, entered a judgment in her favor. The chiropractor then appealed to the district court of appeal, second district, division 2, California.

The sole question before the court was: In case a chiropractor has prescribed treatment for a specific ailment and injures an undiseased portion of his patient's body in no way related to the ailment, may the court, in the absence of expert testimony, properly find that the chiropractor negligently injured his patient? The negligence of a chiropractor, said the district court of appeal, in failing to take due care to avoid injury to undiseased parts of his patient's body may be proved without resorting to expert testimony. The finding of the trial court, based on substantial evidence other than expert testimony, that the patient suffered injuries to an undiseased portion of her body as the result of the defendant's negligence was held to be binding on the appellate court.

The judgment in favor of the patient was therefore affirmed. —*Morrison v Lane (Calif)*, 52 P (2d) 530

**Health Insurance: Total Permanent Disability Defined.**—"Total disability," said the Court of Appeals of Kentucky, does not mean utter helplessness and "permanent disability" does not mean utter hopelessness. A man to be totally and permanently disabled does not have to be reduced to a state wherein he is entirely dependent on others and is absolutely without hope of improvement. In *McNally v United States*, 52 Fed (2d) 440, the United States circuit court of appeals, in defining the term "total permanent disability," said that it does not mean "absolute incapacity" but such "impairment of capacity as to render it impossible for the disabled person to follow continuously any substantially gainful occupation." In the present case the insured, 60 years of age and suffering from heart disease, was held to be totally and permanently disabled, although he attempted to obtain work and actually did work for about twenty days during a period of two years. The sacrifices some men will make, the dangers they will undergo to feed their families, are, said the Court of Appeals, often beyond comprehension. In determining the rights of men, however, the standard of unusual examples should not be used. What the average reasonable man would do under the circumstances is the criterion.—*Actna Life Ins Co v Gullett (Ky)*, 89 S W (2d) 1

**Hospitals, in General: Admissibility of Records in Evidence.**—Plaintiff sued the defendant to recover damages for personal injuries sustained in an automobile accident. At the trial, the court refused to admit in evidence, at the request of the defendant, the hospital records of the plaintiff. The jury returned a verdict for the plaintiff and the defendant appealed to the Supreme Court of New Hampshire, contending that the trial court erred in declaring inadmissible in evidence the hospital records.

Although a liberal rule in regard to the admissibility of entries made in the regular course of business prevails in New Hampshire, said the court, some proof of correctness is required before such entries can properly be submitted to a jury. Ordinarily, verification of the authenticity, regularity and correctness of such records by the official having them in charge would be the minimum of acceptable proof. Whether a record is sufficiently verified to justify its admission, however, is a preliminary question of fact for the trial judge to pass on. In the present case, the records were produced by a nurse who testified that she did not have the custody of the official records of the hospital "except in the absence of the

superintendent." She disclosed no knowledge as to the system or method in accordance with which the hospital records were kept, as to the identity of the persons who made the records in question or the duties of such persons with respect to the recording of facts therein. In short, said the court, no one testified that the records were correct. In view of these facts, in the opinion of the Supreme Court, the trial court committed no error in ruling that the records were inadmissible in evidence. A judgment was therefore rendered on the verdict for the plaintiff.—*Williams v Williams (N H)*, 182 A 172.

**Workmen's Compensation Act: Death from Botulism Compensable.**—Meyer was employed by the defendant Roettele to assist in operating a threshing machine, for which services he received daily wages and board. As a result of the ingestion of a noonday meal, Meyer became ill from botulism and died three days later. The claimants, the parents of Meyer, filed a claim under the workmen's compensation act of South Dakota and the commissioner awarded compensation. This award was affirmed by the circuit court, and the defendants appealed to the Supreme Court of South Dakota.

The workmen's compensation act of South Dakota authorizes an award of compensation "for personal injury or death by accident arising out of and in the course of employment." "Personal injury" is defined specifically to exclude "a disease in any form except as it shall result from the injury." The defendants contended that Meyer's death was due to a disease and that compensation for disease may be awarded only in case the disease is produced or aggravated by an injury caused by an unexpected event. The phrase "injury by accident," the defendants contended, should be construed so as to confine its application to instances in which the cause of the injury was accidental. A disease, said the court, may be an "injury by accident" and therefore compensable. If the element of suddenness or precipitance is present and the disease is not the ordinary or reasonably to be anticipated result of pursuing an occupation, it may be regarded as an injury by accident. The medical testimony was to the effect that the food poisoning and resulting death were caused not by the action of bacteria within the body but by a toxin created by the action of *Bacillus botulinus* on the food before it was ingested. There is no substantial distinction, the court said, between the consuming of this poisonous food and chemical poisoning or the drinking of a virulent poison by mistake. The inception of the disease was attributable to the unexpected and undesigned occurrence of the presence of the poisonous toxin and was assignable to a definite time, place and circumstance. The death was, therefore, the result of an "accidental injury." The mere fact, said the court, that an employee is not actually engaged at his work at the time of injury does not relieve the employer of liability. Under the terms of employment, in the instant case, board was furnished. Meyer was where his employer directed him to be, and, although the partaking of food was personal in character, nevertheless it was so incident to his employment that the accident arose out of and in the course of employment.

In the opinion of the court, however, the award was excessive. The judgment was therefore reversed and the case remanded with directions to enter judgment for the claimants for a lesser amount.—*Meyer v Roettele (S D)*, 264 N W 191

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Relationship of Bacillary Dysentery to Colitis, Ileitis and Granuloma.**—Felsen wishes to show that acute bacillary dysentery, acute distal ileitis, chronic nonspecific ulcerative colitis, ileitis and nonspecific granuloma are but different stages of the same disease. He bases his data on a study of 317 cases of acute bacillary dysentery, eleven cases of acute distal ileitis, forty-two consecutive cases of nonspecific ulcerative colitis, eight with chronic distal ileitis, four with pseudopolypoidosis and two cases of nonspecific granuloma of the ileocecal region. Most of his patients with acute bacillary dysentery recovered completely in from ten days to two weeks. Acute distal ileitis appeared to subside, but in some cases the intestinal lesion persisted. Cases of acute bacillary dysentery lasting for more than three weeks appeared to persist by reason of a secondary nonspecific infection. Contact infection was demonstrated in six cases of nonspecific ulcerative colitis, suggesting that nonspecific ulcerative colitis is transmitted only during the initial stage of acute bacillary dysentery. In forty-two consecutive cases of nonspecific ulcerative colitis a diagnostic agglutination titer against *Bacillus dysenteriae* was obtained. A pathologic study was made of seven specimens of acute bacillary dysentery, eleven of acute distal ileitis, six of chronic distal ileitis, two of nonspecific granuloma and seven of nonspecific ulcerative colitis. The lesions in the chronic stage were identical with those seen in acute bacillary dysentery except that, owing to the long duration of the disease, extensive fibrosis and intramural infection were present. The former represented an attempt at healing and accounted for the loss of haustration and stenosis seen in chronic distal ileitis and nonspecific ulcerative colitis. Nonspecific granuloma of the ileocecal region represents a productive type of inflammation and, like chronic distal ileitis, almost always shows giant cells in the tissue sections. This condition may be erroneously diagnosed as tuberculosis, but tubercle

bacilli are absent and guinea-pig inoculation of the macerated tissue proves negative. While no case of amebic dysentery has been included in this study, it appears to the author that the same type of secondary nonspecific infection might occur. The ideal treatment of nonspecific ulcerative colitis and its related lesions appears to be the prevention of bacillary dysentery. Recognition of the typical and atypical forms of the disease, prompt isolation and careful epidemiologic surveys should lessen the incidence of the diseases known as nonspecific ulcerative colitis, chronic distal ileitis and nonspecific granuloma. Every patient with diarrhea or a history of diarrhea should be placed on typhoid precautions until proved free of *Bacillus dysenteriae*. Most patients with acute bacillary dysentery recover without any specific therapy. Supportive treatment may be used when indicated. The use of recently recovered cases as donors is suggested in the acute severe types of the disease. All patients with acute bacillary dysentery in whom the intestinal lesions persist for more than three weeks should be placed immediately on prophylactic D-C vaccine and antiviral therapy. In sporadic or epidemic outbreaks the widespread use of polyvalent dysentery vaccine should afford some degree of immunity before the patient becomes infected. This observation is based on a limited experience with human contacts and experimental animals. Some cases of nonspecific ulcerative colitis heal spontaneously, but most of them go on for years with periodic stages of remission and exacerbation. All that one can hope for in a case of long duration is subsidence of the infection. Toward this end the author uses the following therapy: (1) intestinal oxygenation, (2) D-C vaccine and (3) D-C antiviral. The organisms in the vaccine and antiviral include polyvalent strains of the specific dysentery (D) organism with which the patient was originally infected as demonstrated by the agglutination titer, and the two common secondary invaders, enterococcus and *Bacillus coli* (C). The vaccine and antiviral are administered every other day, the former in gradually increasing dosage after a preliminary skin test for sensitivity.

**Cardiac Output in Standing Position.**—Scott observed the cardiac output of a single individual in the recumbent, sitting and standing positions. During the winter season in the standing position high auriculoventricular differences are usually associated with high oxygen consumption; in the summer this relationship is reversed. The average standing cardiac output is lower than that of recumbent or sitting positions. The output is influenced by various undefined environmental factors under so-called basal conditions, particularly if the subject is standing.

**Failure of Atabrine to Control an Epidemic of Malaria.**

—In presenting the observations made during the fifth consecutive year of studies on malaria in Panama, Komp and Clark state that none of the methods of treatment used in the preceding year were able to prevent or to check the course of an epidemic caused by subtertian parasites, which occurred during the first four months of 1935. This epidemic was a manifestation of the cyclic variations in malaria parasite rate which are characteristic of malaria in Panama. Increased knowledge of the local conditions has caused them to abandon the method used in the past, the attempt to reduce malaria incidence by treatment directed against the reservoir of malaria in young children and adolescents. They believe that more harm than good has been done by this method and that their objective to increase labor efficiency may be more easily obtained by treatment of clinical cases as they occur, atabrine being used as the drug of choice. Further evidence that a familial immunity to malaria may exist is presented, and, finally, some essential criteria which must be used in future experimental work are outlined.

**Metabolism Studies in Myasthenia Gravis**—To gain information concerning the metabolism of patients with myasthenia gravis before and during the administration of aminoacetic acid Adams and her associates made studies of the food urine and feces of two subjects. In the first period (four days with no aminoacetic acid) for subject 1 the balances for nitrogen, sulfur, phosphorus, magnesium and calcium were close to equilibrium. Likewise during the second period, when

aminoacetic acid was administered for eleven days, there was remarkably little change in these balances. In a subsequent period during which the intake of food and aminoacetic acid was reduced, the balances continued to be much like those observed for the second period. Apparently there was a large retention of sodium in the first period, but this may be ascribed to the fact that the supplementary sodium chloride of the diet was not sufficiently accurately weighed during this period. The retention of sodium in the second period was 0.49 Gm daily, a value not abnormally high in view of the fact that no correction for loss of sodium through the skin could be made. The potassium balance in the first period appeared to be significantly negative. In the second period this balance became somewhat less negative. During the control period, subject 2 was in definite negative balance as regards nitrogen, sulfur, phosphorus and calcium but in approximate balance as regards potassium, magnesium and possibly sodium. During the administration of aminoacetic acid, the second period, the loss of nitrogen decreased but the balance was still highly negative. No marked changes occurred in the balances of the other constituents. The nitrogen distribution during the control periods was apparently normal for each subject, except for the presence of some creatine, a condition occasionally encountered in myasthenia gravis. During the periods of administration of aminoacetic acid there occurred in subject 1 a marked temporary retention of nitrogen for the first day or two. This was later excreted, however, and the average increase in the urinary nitrogen for the entire period was equivalent to 101 per cent of the nitrogen ingested as aminoacetic acid. For subject 2 the increase in the nitrogen of the urine was equivalent to only 81 per cent of the aminoacetic acid ingested. The increased urinary nitrogen was largely in the form of urea. Changes in the other nitrogenous constituents were relatively small and accordingly the nitrogen partition products remained essentially normal. The excretion of creatinine during the periods of administration of aminoacetic acid was unchanged as compared with the excretion during the control periods. Creatine, however, was excreted in definitely increased quantities. The increased excretion of urea, ammonia, creatine, uric acid and amino acids in the periods of administration of aminoacetic acid accounted satisfactorily for all the extra nitrogen appearing in the urine, 100 per cent and 99 per cent for subjects 1 and 2, respectively. The average undetermined nitrogen fractions, therefore, were not appreciably altered by aminoacetic acid and it appears that large amounts of unknown nitrogen-containing substances were not formed, although the possibility of alterations in the character of the undetermined nitrogen fraction cannot be excluded. The excretion of total sulfur and inorganic sulfate by subject 1 during administration of aminoacetic acid was roughly parallel to the excretion of nitrogen, while there was no change in the conjugated sulfate fraction. There was a small decrease in the excretion of total sulfur by subject 2, with a more marked decrease in the inorganic fraction. At the same time the conjugated sulfates increased considerably over the rather unusually low value of the control period. There were rather substantial increases in the excretion of neutral sulfur by both subjects. The excretion of phosphate by subject 1 was markedly increased on the first day of administration of aminoacetic acid but later returned to a level only slightly above that of the control period. The excretion of phosphate in the urine by subject 2 progressively decreased during the period of administration of aminoacetic acid. It seems impossible to conclude that there is any particular metabolic abnormality in myasthenia gravis.

**Treatment of Addison's Disease with Sodium Compounds**—The Reifsteins point out that in treating Addison's disease with sodium chloride it is recommended that the dosage of salt be large from 10 to 15 Gm daily. Divided doses seem to be most suitable, given in milk, capsules or tablets. They have had success with plain uncoated 1 Gm tablets. Enteric-coated tablets should be used with caution, as the coating may fail to dissolve. The extract of the anterior lobe of the pituitary should be tried in addition in refractory cases, as suggested by Wilder. Sodium administered to patients with Addison's disease will either render them symptomless or else minimize the amount of cortical extract required to maintain them in relatively good health. In some cases sodium alone will bring

about a complete remission of a severe relapse. Several patients treated with sodium salts alone still continue to remain well after more than a year, and the span of life of many other patients to date seems to have been prolonged indefinitely. The loss of cortical hormone in Addison's disease apparently removes the normal regulatory mechanism of the blood sodium level, which consequently falls, initiating the train of symptoms attributed to adrenal insufficiency. An associated secondary deficiency in the hormone from the anterior lobe of the pituitary body has recently been suggested. A confirmatory test for Addison's disease of considerable value is the salt-poor diet, which will provoke a typical crisis in a true case of adrenal insufficiency and thereby aid in establishing the diagnosis.

**Leukocyte Picture in Hodgkin's Disease.**—Roth and Watkins made sixty-five differential counts from blood smears in forty cases in which a diagnosis of Hodgkin's disease or lymphosarcoma was confirmed by pathologic study of an excised lymph node. None of the patients had had any previous treatment. The analysis revealed that leukocytosis of slight degree was present in cases in which the duration of the disease was between one and two years. Polymorphonuclear neutrophils were slightly increased in the differential count in cases in which the disease had existed six months or longer. A slight relative decrease in the number of lymphocytes occurred in the same cases. The monocytes showed a greater tendency toward a shift to the right than occurs in normal persons. Extensiveness of the disease apparently does not produce more marked changes in the blood. There is no specific change in the leukocyte picture which is diagnostic of Hodgkin's disease. In the nine cases of lymphosarcoma, the average percentage of polymorphonuclear neutrophils was slightly decreased and the average percentage of lymphocytes slightly increased as compared with the results in cases of Hodgkin's disease. The percentages of other leukocytes and the total leukocyte count were nearly the same as they were in cases of Hodgkin's disease.

**Hemolytic Streptococcus Bacteremia.**—Goldman and Schwartzman classified their 168 cases of hemolytic streptococcus bacteremia according to the port of entry of the organism. Of the 168 patients, ninety-one died. A mortality rate ranging from 60 to 100 per cent was encountered in the following groups: gynecologic infections, articular and osseous infections, miscellaneous nonbacterial conditions associated with hemolytic streptococcus, surgical postoperative infections, pulmonary infections and acute otitis media with meningitis. In contrast to these, the mortality rate of the cases of secondary erysipelas was 20 per cent, of upper respiratory infections 34 per cent, of peripheral infections 36 per cent, of lateral sinus thrombosis 37 per cent, and of primary erysipelas 50 per cent. Of the cases in which the primary foci were located in the respiratory tract, 91 per cent occurred in the winter and spring months. The remaining conditions manifested no particular seasonal influence. Infections of the upper respiratory tract, lateral sinus thrombosis and osseous and articular infections showed a tendency to occur during the early years of life. The other conditions evidenced no predilection for a special age. In the group of peripheral infections the mortality during the

middle years of life was 75 per cent as compared to 25 per cent during the earlier years of life. The quantitative estimation of the number of hemolytic streptococci in the blood stream had both diagnostic and prognostic significance. The conspicuous groups illustrating the diagnostic value of these blood cultures were the cases of lateral sinus thrombosis, infections of the upper respiratory tract and peripheral infections. The prognostic import of these blood culture results is demonstrated by the fact that the groups with relatively low mortality presented a high percentage of positive blood cultures in fluid mediums only, while the groups with relatively high mortality had a high percentage of positive blood cultures in both solid and fluid mediums. Recovery occurred only in the gynecologic and associated nonbacterial cases showing growth in fluid mediums. The ten cases of infection of the upper respiratory tract in which long bone metastases developed manifested a predilection for young children, a tendency toward complete recovery (90 per cent), and a small number of organisms in the blood stream in a majority (fluid mediums only, 60 per cent).

**Bronchoscopic Studies of Lung Abscess.**—According to Goldman, the value of the bronchoscopic examination may be best comprehended by realizing that an abscess of the lung is nearly always at one time or other openly connected with the bronchial tree and that the abscess which occupies a bronchopulmonary segment usually empties directly into a bronchus of the fifth or sixth order. Although the bronchoscope cannot enter the abscess cavity, the examination serves in a useful capacity in localization of the bronchopulmonary segment in which the abscess lodges. Identification of the orifice leads to recognition of the associated segment. Bronchoscopic examination, by visualizing the bronchial orifice, can reveal the position and extent of the pathologic process in the lung and define the area to be exposed by the surgeon. The most reliable single bronchoscopic sign of pulmonary abscess is the escape of foul pus from the mouth of the bronchus. The tracheobronchial tree is frequently congested and swollen. The mucous membrane of the bronchial orifice leading to the abscess is usually red and angry looking. Granulations may be present, or the mucous membrane itself may have a granular appearance. These changes in the mucous membrane are important in the differentiation of the origin of the pus in the bronchial tree, some of which may spill over to adjacent bronchi and make localization more difficult. If the spill-over is observed early, the mucous membrane of the bronchus may be so swollen as to occlude the opening of the bronchus. As the condition progresses into a chronic stage, secondary bronchiectasis develops. The pus from the bronchiectatic cavity is usually foul, but after a long interval the foul odor may disappear. This may indicate bronchiectasis around a shut-off abscess. Other bronchoscopic observations are those of distortion of the trachea, deformity of the carina, obstruction of bronchi, distortions of the bronchi, which are often associated with granulation tissue, and stenosis occurring in the fibrotic stage.

**Acute Laryngotracheitis in Children.**—Smith declares that a selective phase of an apparently mild infection of the upper respiratory tract was shown during the winter of 1933-1934 in and about Los Angeles. As a result, he has collected forty-three cases of nondiphtheritic laryngotracheitis, in

all of which the patient was so ill as to warrant hospitalization. The youngest patient was 6 months of age and the oldest 7 years. The predominating age was from 12 to 24 months. The condition was accompanied by some signs of an infection of the upper respiratory tract. Many of the patients had nothing more than mild pharyngitis or rhinitis for from twelve to forty-eight hours preceding definite symptoms that pointed to an infected and inflamed larynx. Hoarseness was the principal symptom, though it was not always present because the edema is more marked below the level of the true vocal cords. This dysphonia often progressed until a stage of complete aphonia was reached. There was associated a dry croupy irritative type of cough, nonproductive in character. As the edema progressed, the effects of mechanical obstruction became manifest. Retraction took place and was followed by restlessness. As the condition becomes progressively worse, cyanosis develops, which results not only from a limited supply of oxygen but from cardiac exhaustion. It is marked by a paleness rather than the usual blue type of cyanosis. When the latter stage is reached the child is usually moribund and beyond aid. Inspection by direct laryngoscopy usually showed the pharynx, epiglottis and larynx to be hyperemic. No actual membrane was present in any of these cases, although in a few there was a purulent sticky secretion, which adhered to the walls but could be easily removed without any resultant bleeding. In twenty-nine cases the chest was normal. Of the twelve cases in which tracheotomy was performed, there were only five in which positive signs were observed. The temperature, while not greatly elevated, showed evidence of an infection. The red blood cells and hemoglobin were not greatly altered from normal. The hemolytic streptococcus was the predominating organism, but the rapidity of the infection probably did not allow sufficient time for a great change to take place. The white cell count in most cases was in the normal range. Palliative treatment was considered only for the patients with mild involvement in whom retraction was not present or, if so, was very mild and was not increasing. Surgical intervention for the severe form is usually called for, which in twelve patients consisted of tracheotomy. Adequate posttracheotomy care is imperative. Of the twelve patients who required surgical intervention, four died.

**Atherosclerosis.**—Leary obtained diverse aortic lesions at necropsies from his service as medical examiner and supplemented this by aortas from the pathologic service of the Boston City Hospital and from the Children's Hospital. Most of the material was studied in frozen sections, after fixation in solution of formaldehyde, or in fresh sections. He found that all the lesions of aortic atherosclerosis, save the earliest mucoid change, are due to the presence of cholesterol. They are primarily intimal and depend for their nutrition on imbibition through the endothelium. In youth, cholesterol is introduced into the subendothelial tissue of the intima by globular lipophages or is engulfed by globular lipophages in this situation. Young fibroblastic tissue is produced in the subendothelial tissue, and the young fibroblasts engulf and metabolize the lipid, leading to its disappearance from the lesions. Repair with minimal scarring follows, since the young fibroblastic tissue does not form collagen. In middle age cholesterol metabolism within lipid cells is slowed, the connective tissue forms collagen and scar tissue is produced. There is interference with imbibition of nutriment through the scar tissue, and the deep layers

undergo necrosis, with the formation of secondary atheromatous "abscesses" (atherocheumas). Scars are the typical lesions in this period. In old age cholesterol metabolism ceases, globular lipophages accumulate in masses, with inadequate nutrition and support, and a primary atheromatous abscess is the typical lesion. The lesions of the ascending arch are exceptions to these rules, the metabolism of cholesterol being successfully carried on, as in youth, up to advanced ages. The connective tissue that is formed is reticular, as in youth, and minimal scarring is usual. Calcification arises in connection with necrobiosis or after necrosis has developed. It is a terminal monumental deposit marking the sites formerly occupied by living tissue.

**Liver Tissue After Ligation of Hepatic Artery.**—Loeffler did not produce necrosis of liver tissue in rats unless he ligated a branch of the hepatic artery and one of the portal vein at the same time. When partial necrosis occurred in any animal after ligation of the hepatic artery, both the hepatic artery and the portal vein were supposed to be occluded and the blood supply of the corresponding parts completely obstructed. This happened because of thrombosis of branches of the portal vein or of hepatic veins, either directly, through lack of blood supply to the walls of these vessels, or indirectly, owing to necrosis of the wall, caused by extravasation of bile from the necrotic gallbladder or bile ducts in some areas. Obstruction of both vessels in this way resulted in anemic or hemorrhagic infarcts of the liver.

**Protamine Insulin.**—Kerr and his associates used protamine insulin in twenty-five cases of diabetes. They agree with Root, White, Marble and Stotz that, following the administration of protamine insulin, the blood sugar curve is not lowered so precipitately as with regular insulin but slopes off more gradually, is less likely to pass below normal levels and rises slowly to previous levels. The duration of the curve is from two to three times as long as when a similar dose of regular insulin is used. When patients receiving regular insulin are allowed to have a moderate glycosuria, the substitution of an equal dose of protamine insulin causes diminution in the glycosuria, ketosis improves and the patient's feeling of well being is definitely more marked. In the severe cases and in juvenile and the so-called unstable diabetic patients, reactions due to hypoglycemia have been found to be much less frequent with protamine insulin. The authors regard this as one of the main advantages of the new product. In conditions in which more rapid action is desirable, such as coma, regular insulin is to be preferred. Protamine insulin has presented new problems in the administration of insulin; so far the administration of a

dose of regular insulin in the morning and an evening dose of protamine insulin seems to be favored by others. While the authors have found this mode of administration to be satisfactory in many instances, in others different adjustments of dosage and combinations of regular and protamine insulin appear to be more effective in the control of some cases of diabetes. Therefore, further experience with protamine insulin is required before general rules for its use can be formulated. Protamine insulin gives promise of being an important contribution to the restoration of a more physiologic state in the diabetic patient.

**Benign Tumors of the Stomach.**—Van Buskirk states that the occurrence of gastric polyposis is relatively infrequent. The etiology is not definitely known. The condition is often found in association with hypertensive cardiovascular disease, syphilis, tuberculosis, chronic pleurisy and atheroma of the vessels. The microscopic picture consists of hypertrophied gastric glands and varying stages of vascular congestion involving only the mucosa in general, the musculature and the connective tissue being free. Grossly, the tumors are more or less uniform, being soft in consistency and gray, grayish brown or red, depending on the vascularity. They may vary in size from millet seeds to covering the major portion of the stomach. The surface of the tumors may be covered with a thick egg white mucus or hemorrhagic areas of ulceration. At times inspection of the stomach will not be very enlightening, but palpation may give the sensation of the presence of food. That the symptoms of gastric polyposis are not characteristic is revealed by the fact that they are unexpectedly found at necropsy or at operation. At times the duration of symptoms covers a period of years and then occasionally may be very brief, with anemia, loss of weight and strength being the apparent sole manifestations. In some cases a sense of pressure or weight in the epigastrium, progressing to discomfort and abdominal distress, and in other cases abdominal pain are usually the most common complaints. The physical observations are practically negative. The most important procedures revealing conclusive evidence consist of fluoroscopy, x-ray and gastroscopy. In making a diagnosis of gastric polyposis, all factors must be considered and all possibilities must be utilized. In the differential diagnosis of gastric polyposis, carcinoma, extragastric tumors, foreign bodies, hairballs, ulcer, pernicious anemia, functional dyspepsia, sarcoma and syphilis should be considered; but any of these conditions may be present coincidentally with gastric polyposis. In all cases careful roentgenologic examination with accurate interpretation offers the greatest aid in diagnosis. Carcinoma is sometimes found in conjunction with gastric polyposis, one portion of the tumor being benign and the other part undergoing malignant degeneration. Cases with stenosis of the pylorus or obstruction of the pylorus due to a polyp of the stomach, intermittent stenosis of the pylorus due to a gastric polyp, intussusception into the stomach and duodenum due to

a gastric polyp and hemorrhage have been reported as complications. Surgical and adequate reconstructive procedures are indicated in the individual cases and often have changed a diagnosis of malignant tumor to one of benign tumor and given the patient years of good health. When surgical removal is possible, roentgen therapy and radium may prove beneficial.

**Hematogenous Acute Osteomyelitis in Children.**—Wilson and McKeever discuss the effect of early and late operations, with regard to the mortality and development of secondary foci, on 110 patients suffering from hematogenous acute osteomyelitis, exclusive of the bones of the head and the face. The data suggest that perhaps the answer to the problem is not the earliest possible surgical invasion of the bone, but a well timed adequate drainage of the medullary canal when the patient's resistance is at the highest possible point. It has been their repeated experience that an acutely suffering child who enters the wards in a badly dehydrated condition with a very high temperature and pulse rate will become a vastly better operative risk in twenty-four, forty-eight or even seventy-two hours, during which time the suffering has been relieved and the dehydration overcome. The improvement in the general condition will be obvious. The lesion will probably be quite evident when the child enters the hospital, as will the eventual necessity for an operative procedure; but timing is the important factor in treating acutely sick children. A blood-borne infection of bone may be more successfully handled by adhering to the principle of allowing the infection to localize. A catastrophe may result from a too early osteotomy of an infected bone, for the same reason that incision of a brawny cellulitis is often fatal. On the other hand, it seems unwise to permit a patient to harbor a well formed abscess for days or to drain such an abscess only partially and imperfectly. Such procedures favor the formation of multiple metastatic lesions, as is evidenced by the preponderance of these lesions in cases in which only incision of the soft tissues was carried out, or those in which spontaneous rupture of the abscesses was permitted.

**Treatment of Chronic Osteomyelitis.**—Armstrong and Jarman conceived the idea that skin grafting might be applied in promoting the rapid epithelization and healing of bone cavities left after radical operative treatment of chronic osteomyelitis. Prior to the adoption of this method some eight years ago, these cavities had been treated by packing with sterile gauze in the

ordinary way, and it was noted that the granulations grew much faster from the peripheral parts of the cavities than from their depths, which often resulted in the formation of small deep-lying sacculi connected by a narrow track with the superficial surface of the granulation tissue. These sacculi were responsible for the persistence of multiple points of discharge on the surface of the granulation tissue and therefore failure of epithelization. The method described obviates this disadvantage and promotes really rapid epithelization. The first stage consists of saucerization of the diseased area and the second stage of skin grafting of the cavity, Esser's plan being used of applying the grafts on a mold of Stent's dental composition. The authors do not claim that the end results are superior to those obtained by the Orr method but that their method has the advantage of promoting faster epithelization and healing and that there is no unpleasant odor associated with it. It has occurred to them that this method might, with advantage, be applied during Baer's maggot treatment at that stage when the wounds are filled with healthy, red granulations, when the reaction of the wound discharges is alkaline and when pathogenic bacteria are few. The deep but completely epithelized cavities which result from this method of treatment tend to diminish with the passage of years.

**Pathologic Dislocation of Sacro-Iliac Joint.**—L'Episcopo reports a case of true pathologic dislocation of the sacro-iliac joint. He doubts whether the suppurative condition alone was responsible for the dislocation, because the os innominatum cannot slide upward on the sacrum unless there is also a separation at the symphysis pubis, so that there must be a loosening of both these joints for the condition to occur. The patient gave a history of having a spontaneous abortion a few weeks before the onset of the acute infection of the sacro-iliac joint. She was about two months pregnant at the time. Probably because of the action of some hormone there is a relaxation of all the pelvic joints during pregnancy. However, relaxation of these joints takes place in a lateral direction. Because of the preexisting physiologic relaxation at the symphysis pubis, it is the author's belief that the coincident infection of the sacro-iliac joint, with resulting destruction in that joint, was responsible for the upward displacement of the os innominatum on the sacrum.

**Magnesium Needs of Preschool Children.**—Daniels and Everson made thirty-three magnesium, calcium and phosphorus balance studies in thirteen children between 4 and 7 years of age, who received varying amounts of magnesium as well as calcium and phosphorus. Each balance study, with one exception, has consisted of a preliminary period of six or seven days to allow for adjustment to a given ingestion level, and a double metabolism period of five days each, thus minimizing unavoidable errors from inaccurate stool marking. Each day's food

consisted of milk, meat, eggs, potatoes, prunes, apple sauce, banana, carrots, breakfast cereal, bread, butter and 1.5 Gm. of iodized table salt, distributed among the three meals. Distilled water was used for drinking and cooking purposes. The question of vitamin D or C deficiency was ruled out by 3.6 Gm. of cod liver oil and 4 drops of viosterol twice daily, with a given amount of orange juice and 120 Gm. of canned tomato. Variations in the level of magnesium were obtained by altering the amount of milk and cereals in the diets. The methods for the calcium and phosphorus determinations were the same as those of a former study. Magnesium determinations were made with filtrates from the calcium precipitates by the method described by Epperson. The magnesium ingestions of the children studied were between 11.3 and 19 mg. per kilogram, whereas the magnesium retentions ranged between 0.4 and 3.1 mg. per kilogram. High retentions were not consistently associated with high ingestions, nor were low ingestions always followed by low retentions. Calcium:magnesium ingestion ratios ranged between 2.8 and 6.7, whereas calcium:magnesium retention ratios were between 3.8 and 30.3. The magnesium of the urine, which tended to parallel the magnesium ingestion, suggested that this might be used as a means of determining the sufficiency of the diet in this respect. Low urinary magnesiums, when coexistent with low retentions, were indicative of too low ingestions. High urinary magnesiums with low retentions were interpreted as indicating that enough had been fed and that previously the individual had been receiving a diet containing a sufficient amount, whereas high urinary magnesiums with high retentions following high ingestions indicated that the individual had been receiving previously less than the optimal amount. Seventy-five per cent of the children studied were in this group. It was concluded tentatively that diets of children of the ages studied should contain not less than 13 mg. of magnesium per kilogram of body weight.

**Vitamin Content of Canned Pineapple Juice.**—Guerrant and his associates made a biologic assay of canned pineapple juice for its vitamin content, using standard biologic methods, which showed this juice to be a good source of vitamins A and B and a fair source of vitamin C, and to contain a measurable quantity of vitamin G. When expressed in terms of vitamin units, 1 ounce of the juice contained approximately 30 Sherman units of vitamin A, 20 Sherman units of vitamin B, 2.5 Sherman units of vitamin G, and four minimal protective doses or 40 international units of vitamin C.

**Effect of Ephedrine on Erythrocytes, Leukocytes and Platelets.**—Simpson and Cadness gave female guinea-pigs weighing from 300 to 400 Gm. subcutaneous injections of ephedrine hydrochloride in a 2 per cent aqueous solution. The dose used was 2 mg. per hundred grams of body weight. Specimens of blood were obtained by pricking the small vessels of the ear before injection and subsequently at intervals of two

hours for a period of from twelve to twenty-four hours. The duration of the effect of the ephedrine was indicated by the persistence of exophthalmos and erection of hair. The usual methods of enumerating the different cell elements were employed. For the experiments on splenectomized pigs the spleen was removed under pentobarbital sodium and ether anesthesia, and the postoperative effect of ephedrine on the blood was ascertained after a period of ten days, in which time the guinea-pigs appeared to have made a complete recovery. In normal guinea-pigs the erythrocytes were increased by more than a million, the leukocytes by some 10,000 and the platelets by almost a million. The hemoglobin, although raised 17 per cent, did not increase to quite the same extent as the erythrocytes (22 per cent). The initial leukocytosis was associated with a preponderance of lymphocytes, but subsequently there was a progressive increase in the proportion of polymorphonuclear neutrophils. The maximal numerical increase was attained first by the erythrocytes, then by the leukocytes and finally by the platelets. The increases in the total number of erythrocytes, leukocytes and platelets in splenectomized guinea-pigs were of the same order as those obtained in the normal guinea-pigs. With increasing skill in the performance of splenectomy, the operation did not appreciably affect the blood count when taken after a period of ten days. The conclusion is that the spleen is not essential for these changes in the guinea-pig. In addition to other evidence the disproportionate increase in the different cell elements indicated that "blood concentration" is not an adequate explanation of the changes. Ephedrine probably causes extrusion into the circulation of erythrocytes, leukocytes and platelets from storage and hematopoietic centers, including the bone marrow.

**Posterior Lobe Pituitary Principles and Insulin.**—Ellsworth offers evidence that mild insulin hypoglycemia in dogs can be abolished completely by small doses of the oxytocic principle of the posterior lobe of the pituitary; corresponding doses of the pressor fraction have little or no effect. Larger doses of the oxytocic principle not only abolish the effect of insulin but cause a rise in the blood sugar level above normal.

**Undiagnosed Syphilis.**—As an aid in the diagnosis of syphilitic infection, Bainbridge used definite changes of the hands observed roentgenographically, though there may not be any symptoms in this region or any general evidence of the disease. He quotes Riley and Smith: "An important finding both in acquired and congenital syphilis, which so far as we know has not been recognized and which is oftentimes of very great value in deciding the diagnosis, is the occurrence on the phalanges of the subperiosteal budding and resorption areas without necessary relation to any other syphilitic pathology. These may be so slight as to be either overlooked or disregarded till their diagnostic importance is realized. Even with a negative Wassermann reaction, so frequent with bone syphilis, their occurrence is a definite indication of syphilitic infection." This pathologic change is noted along the shafts of the phalanges and does not occur at the joints to be confused with arthritis. A combination of the areas of budding and resorption, and arthritic changes may be present in the same case and make the diagnosis doubly difficult. In addition, in these cases of possible syphilitic infection, at times, there is an

irregularity of the cancellous tissue and in the alinement of the compact tissue surrounding it. Often the changes are so slight that a high powered magnifying glass must be employed to detect them. The roentgenologist, looking for gross lesions, frequently does not observe these changes, or discounts their presence as of no significance and submits a negative diagnosis. The author has found this diagnostic adjunct to be of assistance in deciding doubtful cases, or as a lead to the diagnosis in some heretofore unsuspected ones. In cases in which the serologic tests have been weakly positive but definite areas of budding and resorption existed, he has been led to give a provocative Wassermann test, with the observation that in most of them a positive reaction occurred. Whether or not the blood or spinal fluid confirmed the roentgen observations, in many cases in which the latter have given apparent evidence by the areas of budding and resorption—really scars—of a specific infection, antisyphilitic treatment has been instituted, and the beneficial results proved the accuracy of the diagnosis.

**Air-Tight Drainage of Nontuberculous Empyema.**—Santillan and Perez treated six cases of acute empyema by air-tight drainage. One happened to be of tuberculous and pneumococcal origin and another developed pyarthrosis of the left shoulder, which proved fatal. The treatment is started a few days after the onset of the empyema. The method used by Bettman is adhered to. The site selected is the eighth or ninth interspace at the posterior axillary line. The space selected need not necessarily be the most dependent portion of the cavity. In fact, this may be a handicap; for, when the diaphragm rises as the cavity of the empyema diminishes in size, the tube which is at the bottom will necessarily be pressed by the rising diaphragm. The site is anesthetized locally with procaine hydrochloride, an aspirating needle is inserted, a small amount of pus is aspirated to insure success, a small slit is made in the skin, and a trocar admitting a No. 14 French catheter is inserted. The trocar is gradually introduced perpendicularly to the thorax. When the cavity is reached the obturator is pulled out and the lubricated catheter is inserted immediately. The flaring edge of the catheter is cut and rethreaded on the same catheter in order to keep it in place. Dressings are applied. The pus is aspirated every three hours and from one third to one half of its volume is replaced by

dilute solution of sodium hypochlorite. After one week if airtightness is lost another catheter, one size larger, is inserted. By introducing catheters of increasing sizes, the cavity is kept almost continuously air tight. When the fever drops, which usually takes place in from one to three weeks, the patient is permitted to walk, to take bending exercises and to blow rubber balloons. Before doing so, the free end of the tube is connected with a two-holed, wide-mouthed bottle half filled with dilute solution of sodium hypochlorite. A pocket is made on one side of the patient's binder and the bottle is put in it. By this method the patient can walk around with ease and comfort. When this stage of the treatment is reached the aspiration is done only once or twice daily. The siphonage into the bottle replaces the aspiration, and the patient may be discharged from the hospital and be treated at home or at the clinic.

**Roentgenologic Changes in Malacic Diseases of Bone.**—Camp classifies the causes of malacic diseases of bone ("hyperparathyroidism") into atrophy, congenital defects, dietary insufficiency and avitaminosis, renal insufficiency, endocrine malfunction and miscellaneous conditions of unknown etiology. 1. Atrophy of bone, which results from disuse incident to trauma, fracture, arthritis, neurotrophic disorders or circulatory disease, is characterized by its limitation to the affected part. 2. In congenital defects are placed cases in which the bones are fragile because of a failure on the part of certain primitive cells to differentiate into their normal tissues. The basic defect appears to be an inability to form osteoblasts. The entire skeleton is affected. The bones have a bowed, misshapen, shortened and thickened appearance. Callus is easily detected in the shafts at the sites of fracture. Compression of the thorax and fracture of the ribs are common. Ossification in the skull is deficient and irregular. A bitemporal and occipital protuberance of the skull is common. 3. Rickets and osteomalacia constitute the lesions in dietary insufficiency and avitaminosis, which result from a deficient supply of calcium or phosphorus in the food or a deficient intake of vitamin D. There is little doubt that they are one and the same disease, except that rickets affects the growing child and osteomalacia the adult. In osteomalacia the significant roentgenologic changes consist of generalized osteoporosis, marked thinning of the cortical bone, with softening, bowing, fractures, kyphosis and generalized deformities. Of particular interest are the transverse osteoid zones, described by Looser, which simulate pathologic fractures. They usually occur in cases in which the disease is well advanced, and they have a tendency to be symmetrically distributed. Osteomalacia, especially the senile variety, is frequently confused roentgenologically with

the skeletal changes of hyperparathyroidism. Cysts, however, do not occur in osteomalacia, and the transverse osteoid zones, which are so common in osteomalacia, are not observed in hyperparathyroidism. In doubtful cases blood chemistry and even biopsy of a bone may be necessary to distinguish osteomalacia from hyperparathyroidism. 4. Renal dwarfism occurs in children, in association with chronic renal insufficiency and apparently as a result of it. The stunting of growth and delayed union of epiphyses may be complicated by a rachitic process, which has all the clinical, roentgenologic and histologic characteristics of true rickets. Skeletal development is always retarded. There usually is something atypical: the lesions may be asymmetrical or different bones may be involved unequally. In cases of long duration there is a deep mottled zone at the ends of the long bones, which consists of osteoid tissue, cartilage, fibrous tissue and calcified matrix. Distortion, inflections and various deformities may result. In advanced cases the granular appearance more closely simulates the granular osteoporosis of hyperparathyroidism than does any other malacic disease of bone. In renal rickets the nephritis antedates the skeletal changes, whereas in hyperparathyroidism the skeletal changes usually antedate the nephritis. 5. Under endocrine dysfunction are hyperparathyroidism, hyperthyroidism, Cushing's syndrome, suprarenal disease, pancreatic disease and carcinoma of the pancreas and pancreatitis. 6. The miscellaneous conditions of unknown etiology include focal osteitis fibrosa cystica, osteitis deformans (Paget's disease), disease of the reticulo-endothelial system, Gaucher's disease and blood dyscrasias. Because of the multiplicity of conditions that may affect the mineral content and structure of the skeleton, the early recognition of any particular disease by roentgenograms alone may be exceedingly difficult.

**Pathogenesis and Radiotherapy in Carcinoma of Thyroid.**—According to Levin, in view of the pathogenesis and mode of formation of carcinoma of the thyroid, the therapy in the early stage of the disease is, in reality, the therapy of benign goiter. If evidence is found of proliferative activity, surgical removal should be followed by a course of radiotherapy over the operative field and also over the regions of the skeleton in which the skeletal metastases usually develop. In postoperative radiotherapy of carcinoma of the thyroid, the author employs radium in the operative field and high voltage roentgen therapy over the chest and skeleton. When the condition is in an advanced stage and a hard nodular tumor is present, invading diffusely the thyroid and firmly adherent to the underlying tissues of the neck, the treatment of choice is radiotherapy. The method consists in an incision over the tumor, a biopsy, and, depending on the size of the tumor, either buried gold seeds or the insertion of removable platinum needles. The objective is to destroy all the carcinomatous tissue, which must be accompanied by the destruction of the remnants of the normal thyroid tissue. As a result, there always develops a certain degree of myxedema. This complication proves that a good therapeutic result was obtained. Carcinoma of the thyroid functions in the same manner as a normal gland. Whenever such a myxedema disappears without treatment, it is an indication of either local recurrence or metastasis.

**Effects of Occipital Lobectomy on Vision in Chimpanzee.**—Spence and Fulton subjected an adolescent chimpanzee to complete extirpation of the left occipital lobe and extirpation of the posterior and lateral portions of the area striata of the right hemisphere. The removal of the entire left area striata resulted in a slight but consistent loss in visual acuity ranging from approximately 5 to 15 per cent at four brightness levels. Following the second operation, which left the animal with only the anterior portion of the right area striata intact, there was complete failure to discriminate a pattern sixteen times as large as that discriminated in the preoperative tests. Rough testing of the visual fields suggested that a right homonymous hemianopia resulted from the first operation, while the second spared only the extreme left peripheral fields; i. e., the temporal halfmoon. The latter result supports the view that the occipital pole of the area striata represents the macular projection area and that the anterior portion of the area striata around the calcarine fissure is the cortical terminus of the extreme peripheral retinal elements.

**Familial Schilder's Disease.**—Meyer and Tennent present the clinical and pathologic records of two brothers suffering from Schilder's disease. Their mother is affected by a progressive spinal condition, the nature of which is still uncertain. Gastro-intestinal troubles preceded by a long interval the nervous disorder of the two brothers. These symptoms are also presented by a third brother who has slight ataxia. There were no histologic changes in the visceral organs to account for the condition of the central nervous system. The pathogenic and etiologic views on Schilder's disease are discussed in the light of the cases investigated. Consideration is given to the theory of primary glial disturbance with especial attention to the difficulties of interpretation of the histologic data. The peculiar distribution of the process in the optic tract is described. It was similar to that described by Scherer in a spontaneous disease in monkeys. The nosologic significance of these symptoms and of "honeycombed" patches, which are found also in Schilder's disease, is discussed as to its broader aspects.

Seventeenth Century Cure for Rickets. W. J. Rutherford.—p. 40.

**Chronic Jaundice and Hypertrophic Cirrhosis of Liver and Infantile.**—Chand gives the details of three cases of chronic jaundice with hypertrophic cirrhosis of the liver and infantile in blood brothers. Two of them are alive and the third, the eldest, has since died. The clinical features tally in almost all respects with those of Hanot's cirrhosis and cannot be accounted for by conditions like Banti's disease, acholuric jaundice and chronic infective cholangitis, with or without ordinary cirrhosis. In the patient who died, signs and symptoms of portal cirrhosis appeared in addition to those of biliary cirrhosis a few months before death. Biopsy or necropsy could not be done to study the pathologic changes of the disease.

**Neonatal Dermatitis.**—Carter and Osborn state that "pemphigus neonatorum" is a contagious, subepithelial dermatitis, with an incubation period of one or two days. The lesion is situated under the epidermis and tends to spread centrifugally unless a reliable antiseptic is brought into immediate contact with the infecting organism. As the source of the outbreak may be difficult to find, the disease tends to become epidemic. In a maternity unit in which this disease is endemic, irregular waves occur in the graph of the cases; the number of cases increases with rush work in the department and drops in the quiet periods. The elimination of the source of infection is the ideal and only sound method of checking an outbreak. The disappearance of cases of folliculitis at the same time as those of pemphigus suggested that the etiology is somewhat similar, and histologic sections showed that the lesion of pemphigus was subepithelial and therefore more dangerous. It should be possible by early diagnosis and intelligent and effective treatment to lower and practically to abolish the mortality of the disease. The presence of pemphigus in a maternity unit is an indication that there is a septic focus in or associated with that department, and the septic focus should be found and eradicated. In the outbreak of pemphigus at Mill Road Infirmary at least seventeen strains of *Staphylococcus aureus* and two of *Staphylococcus citreus* were found. Pemphigus neonatorum should have only one phase, that of the small unbroken blister. If treatment by silver nitrate is followed, subsequent phases should not occur. The authors are convinced that this disease is not an acute infective fever but merely a local subepithelial dermatitis, and that local treatment can abort it. They protest against the totally erroneous dogma that fatal cases are doomed from the onset. Fatal cases are due to late diagnosis and inefficient treatment.

\*Chronic Lead Poisoning Due to Theatrical Grease Paint. E. L. Bartleman and C. Dukes.—p. 528.

**Lead Poisoning Due to Theatrical Grease Paint.**—Bartleman and Dukes report the case of a young actress who developed the classic symptoms of lead poisoning. Blood examination revealed anemia and stippled red cells. The diagnosis was confirmed by the finding of large quantities of lead in the urine and feces. The source of the lead poisoning was traced to the use of a grease paint containing approximately 40 per cent of lead. Traces of lead may be found in the urine of healthy people. This is due to the fact that small quantities of lead are ingested with such food as sausages, meat, beans, cherries and other fruit. This being so, it is obviously unsafe to base a diagnosis of lead poisoning on the discovery of lead in the urine unless this is estimated quantitatively and found to be far above the normal limits. Actually in lead poisoning the patient usually excretes at least 0.1 to 0.3 mg. of lead per liter, and, when figures such as these are reached, there is strong evidence for lead poisoning. In the present patient the quantity of lead excreted was more than ten times the normal, so that the test provided confirmatory evidence. However, in view of the pitfalls that may beset diagnosis by urine

tests it is important to recollect the paramount importance of the clinical history and blood picture. The stippled red blood cell is easily recognized in a Leishman-stained film. Anemia in association with a high stippled red cell count should always suggest lead poisoning. The two conditions in which the blood picture mostly resembles lead poisoning are acholuric jaundice and chronic malaria, in both of which the reticulocyte count is commonly higher than normal. There is a great variability in susceptibility to lead poisoning. The grease paint used by the patient was the same brand as that used by several other members of the cast, but so far no other case of lead poisoning occurred. There were, however, a good deal of ill health and complaints of tiredness and headaches among those of the cast who had used this grease paint previously.

**Treatment of Bacillus Coli Pyelitis with Alkalis.**—Osman declares that the successful treatment of Bacillus coli pyelitis with alkalis depends chiefly on careful attention to detail: essential factors in the method are the production of a copious diuresis and a sufficiently alkaline urine. Clinical trials show that neither alone is effective, though the mechanical flushing out of the urinary passages is probably the more important of the two. A certain degree of alkalinity of the urine tends to inhibit the growth of Bacillus coli-communis, though it may flourish sometimes in exceedingly alkaline urines, especially in vitro. Recent observations suggest that inhibition of growth of the bacilli is more satisfactorily accomplished when the urine has been rendered unusually acid, as with a ketogenic diet. But the precise significance of the reaction of the urine in relation to the growth, or inhibition of growth, is not yet known. Alkaline therapy can be continued indefinitely without harm to the individual or serious interference with the activities of a normal existence; it permits of a normal diet being taken, and, above all, it confers protection against relapses so long as it is conscientiously carried out. Nevertheless, it is of little use in cases with increasing urinary obstruction, as in the later stages of pregnancy, or in cases in which mechanical deformities of the renal pelvis or ureters cause stagnation of urine. It is of doubtful value, therefore, in cases with chronic ulceration and scarring of the renal pelvis, neuromuscular incoordination or congenital anatomic defects of the pelvis or ureters. Such cases can be cured only, if at all, by inhibiting the growth of the localized bacilli, and it is in these cases that the ketogenic diet or mandelic acid should be tried.

**Glomerulonephritis Produced by Specific Serums.**—Arnott and his associates repeated the experimental production of glomerulonephritis in rabbits in accordance with Masugi's method. They deal principally with the histologic observations in their first group of animals subjected to injections of anti-serum. They anesthetized rabbits of varying breeds with ether, opened the abdomen, cannulated the renal artery on each side and perfused the organs with sterile saline solution until

free of blood. The kidneys were then removed and ground in a mortar. Physiologic solution of sodium chloride was added in sufficient quantity to give a final suspension of from 10 to 30 per cent. Subsequently the suspension was injected intraperitoneally in 10 cc. doses into Aylesbury ducks. This procedure was repeated at intervals of from four to five days on from twenty-five to forty occasions. At the end of this period each duck was anesthetized and the sternum removed. With a wide bore needle as much blood as possible was aspirated from the right ventricle. The blood serum was heated to 56 C. for thirty minutes in order to eliminate natural complement and was then ready for use. The results show that a serum prepared in the foregoing manner causes a glomerulonephritis similar histologically, in all essential features, to human glomerulonephritis. Clinically there is also great similarity, even to the production of hypertension, although the latter point has not yet been established as blood pressure observations were carried out in only one animal. This point is the subject of further research. Further research is also being carried out on the effect of serum prepared by repeated injections of liver tissue. Masugi, working with rats and rabbits, claimed that such a serum caused specific damage to the vessels of the liver, while it did not damage the kidney. The demonstration of an organ specificity in this immune serum would in itself be a matter of considerable importance, as this possibility is generally regarded as unlikely. An immune serum with little or no tissue specificity might cause almost exclusively glomerular damage, because the glomerular capillaries pass through their walls far more diffusible substances than any other group of capillaries in the body. The one point of contact so far established between the mechanism of human glomerulonephritis and that of this experimental glomerulonephritis is the fact that the human disease seems to occur in cases of streptococcal infection in which there is a vigorous antibody response resulting in an unusually intense antigen-antibody reaction while, in the experimental lesion, there is undoubtedly an intense antigen-antibody reaction occurring in the rabbit.

**Prognostic Value of Variation in Arneth Count in Cases of Asthma Treated with Autovaccine.**—Napier and Dharmendra discuss the changes in the Arneth counts produced by means of treatment with autovaccine in twenty-five cases of asthma. A vaccine made from the organisms isolated from the sputum was used and a course of six injections was given. The first count was done on admission of the patient to the hospital and the second about two days after the last dose of the vaccine. The Arneth count on the first occasion showed a marked shift to the left. At the second examination the count showed an even more marked shift to the left in three cases, no change in two cases and a decrease in the shift, either slight or marked, in twenty cases. When the variations in the Arneth count on the two occasions are correlated, the relation between the improvement in the condition of the patient and the improvement in the shift to the left in the count becomes prognostic. The initial Arneth count gives little information about the results to be expected from vaccine treatment. The Arneth count after the treatment gives some information on this point. The fall of the Arneth index below 80 seems to

be a favorable prognostic sign. The extent of fall in the index after the treatment gives the most information regarding the prognosis. Among the cases not responding favorably to the treatment, the index sometimes rises and in no case shows a marked fall. In the cases showing temporary improvement, the fall in the index never exceeded 10 points. A fall of 10 or more in the Arneth index after the treatment with auto-vaccine is a good prognostic sign.

**Rôle of Bacillus and of "Hetero-Allergy" in Tuberculous Liquefaction.**—Pagel is of the opinion that tuberculous liquefaction is an allergic phenomenon. The presence of bacillary bodies is necessary for its development, for these, as an antigenic irritant, give rise to the allergic reaction. The allergic reaction that causes liquefaction of the implanted material seems to be closely connected with tuberculous hypersensitiveness, such as occurs in Koch's phenomenon. It is justifiable to assume that the early stage of tuberculous liquefaction in man follows an increase in the number of bacilli; this provides the irritant requisite for the allergic reaction. The foreign body reaction occurs earlier in tuberculous than in normal animals. In tuberculous hypersensitive animals, moreover, the introduction of an artificial substitute for dead tissue, without tubercle bacilli but containing such substances as develop during their growth in glycerin broth, causes within from four to six days the formation of a granulomatous lesion with giant cells of the Langhans type, which corresponds to an allergic modification of the foreign body reaction (hetero-allergic reaction). These features are absent in the impetuous

allergic reaction that occurs in response to the injection of an artificial substitute for tissue but containing also bacilli. Increase in the protein content of the injected material generally gives similar results. Exceptional hyperergic reaction to the filtrate is a hetero-allergic phenomenon, as proved by the injection of pure protein mixed with glycerin broth. Hetero-allergic reactions in the model experiment do not give any information as to the production of liquefaction by specific substances in the tissues of tuberculous foci, or as to the part played by hetero-allergy in tuberculous liquefaction of man.

**Paralysis of Diaphragm in Treatment of Tuberculosis.**—O'Shaughnessy and Crawford do not consider phrenic evulsion, discreetly and carefully performed, a dangerous operation but have adopted phrenicosthasty, the procedure of which is described, on quite other grounds. They have observed an increasing number of patients with bilateral phthisis for whom some form of bilateral collapse operation would offer a prospect and the only prospect of cure, but a paralyzed diaphragm has ruled out such a possibility. In the young patient a paralyzed hemidiaphragm does not produce signs of respiratory distress. But it has been suggested recently that in middle age paresis of the diaphragm may constitute a more serious handicap: Kochs found that phrenicotomy produced a greater reduction of vital capacity in middle aged than in young patients. The possible detrimental effects of the paralysis on cardiovascular function in later life must also be borne in mind, and the recent experiments of Nissen and Wustmann on the effect of diaphragmatic movement on the caval blood flow are of interest in this connection. The authors therefore believe that it is of probable advantage for the patient to have a healed tuberculous lesion and a moving diaphragm; for, should the lesion again become active, the patient is a suitable subject for any form of treatment that may be necessary, and if, on the other hand, the disease remains permanently arrested, there is no chance of his having to pay for this benefit by an impairment of respiratory or cardiovascular function in later life.

**Skin Disorders Underlying Pruritus of Vulva and Anus.**—According to Hunt, the diagnosis of a disorder of the skin, when it is localized on or around the external genitalia and anus, may be and often is extraordinarily difficult, for the distinctive characters of the eruptions are wont to be modified in this moist warm area, and it is sometimes only by the discovery of typical lesions at other sites that the diagnosis can

be made with confidence. The need for accurate diagnosis and for the differentiation of the various skin disorders that may give rise to vulval and anal irritation must be apparent not merely for the purposes of treatment but also for the reassurance of the patient and for guidance in avoiding recurrences. An analysis of 300 cases of pruritus falls into seven groups: general disorders of the skin (lichen planus, seborrheic dermatitis, psoriasis, eczema and leukodermia), dermatitis traumatica and venenata, local causes, parasites, general constitutional diseases, psychic and miscellaneous (lichenoid eruption, senile pruritus and hygienic laxity). The most striking feature was the large number of cases presenting well known disorders of the skin, and in particular the excessive proportion of cases of lichen planus—an eruption that may affect skin and mucous membrane and usually stated to occur rarely on the vulva.

**Intraspinal Injection of Alcohol for Intractable Pain.**—During the last eighteen months Russell has used the intraspinal injection of alcohol in attempting to relieve severe pain in eighteen cases, and in several of these the result of the injection has been satisfactory. The dangers of the injection, the technique for the relief of sacral pain and the method of relieving lumbar or thoracic pain are discussed. In the cases treated the injections given were in many instances larger than those advised. The first injections were small (0.5 cc) but had no effect in relieving severe pain, hence in cases of advanced cancer the author has given injections of 1 cc or more. Most of the patients treated had advanced malignant disease, and most were in the cancer wards of a hospital for patients with incurable diseases.

Progress and Problems W M Eccles—p 304

**Hypervitaminosis in Country Children.**—Ball discusses the occurrence of cases which in towns are deficiency diseases but which occur in the country in the opposite type of patient. Three types of case (anemia, phlyctenular conjunctivitis and debility) are differentiated from the clinical point of view. The patients usually respond to an increase in the carbohydrates in the form of sweets and cakes, and diminution, or even absence, of vitamins in the form of cod liver oil and fresh fruit. The children that were reared in the best conditions were often of poor type, while those who were reared on a definitely deficient diet were healthy and rosy cheeked. In this series of cases the three types of patients that are successfully treated in towns with sunshine and an increase of vitamins were successfully treated in the country with the exactly opposite treatment. It would seem that an excess of vitamins can bring about the same clinical picture as a lack and this stresses the danger of indiscriminate dosing with cod liver oil and the like.

**Tubal Factor in Sterility Among Chinese Women.**—King investigated 272 cases of sterility in Chinese women by means of uterotubal insufflation, using air or carbon dioxide. There were 165 instances of primary and 107 of secondary sterility. The result of insufflation depended to a certain extent on the method used. Normal tubal patency and absolute tubal nonpatency could be demonstrated with equal ease by either method, but impaired patency associated with tubal spasm, stricture or stenosis could not be clearly differentiated by the simple air insufflation method, whereas it was plainly shown by the kymographic method. Chronic inflammatory disease of the tubes was responsible for practically all cases of impaired patency or complete nonpatency. The gonococcus was comparatively rarely obtained in smears, owing to the chronicity of most of the cases. In the majority of the cases of nonpatency, however, there was a history suggestive of gonococcal infection in either the patient or her husband, commonly in both. Tubal insufflation possesses therapeutic as well as diagnostic value. Pregnancy is known to have occurred in sixteen patients following insufflation. Since only between 30 and 40 per cent of all cases of insufflation could be followed up, the actual incidence of pregnancy in the series must be higher than this.

**Pigmentation of Skin Following Gold Treatment.**—The pigmentation of the skin occurring in the course of gold treatment is, according to Cardis and Conte, a relatively new disorder. Age appears to have no influence on its appearance, but it is much more common in women than in men. The nature of the gold salt is relatively immaterial, but the dose is important since the cutaneous pigmentation has generally appeared after enormous doses. It is more common in blondes than in brunettes. As a rule, the onset is insidious and progressive and difficult to determine. In general, it appears after one or two years of gold therapy. The pigmentation affects especially the eyes and the face. The degree of pigmentation varies from day to day. It develops almost always either toward a stationary position or a progressive aggravation. Examination of a fragment of skin has been performed in three instances to the knowledge of the authors. Small grains of gold have been found in the pigmented skin. Small plaques of histiocytes with pale nuclei and innumerable granulations have been found in the spleen. Other viscera have been found similarly infiltrated with gold. No certain treatment is yet known. The authors conclude that it is wise to avoid large doses of gold, especially in blonde women, who are particularly susceptible.

**Air, Sea and Train Sickness.**—Lenggenhager cites observations and experiments which indicate that sea, air and train sickness is not caused by the labyrinth but by the fluctuations in the pressure and traction exerted on the large nerve plexuses of the sympathetic system in the epigastric region. Regarding the treatment he says: 1. The horizontal position of the body greatly protects against sea or air sickness. 2. An empty stomach and small intestine reduce the shifting and pressure changes in the viscera. To be sure, this advantage is interfered with by the fact that a newly filled stomach produces a pleasant drowsiness (reduced sensitivity of the nervous system). The latter factor explains why persons on a sea voyage usually feel well shortly after eating. 3. Strong lacing of the abdomen slightly reduces the shifting of the viscera. 4. Substances that have a paralyzing effect on the nerves inhibit sea sickness. However, since irritation of the vagus is not the only cause of sea sickness, combination preparations are advisable.

\*Eleomas and Subcutaneous Lipoid Necrosis. E. Repetto.—p. 495.

Syphilitic Myocarditis. L. Lami.—p. 500.

**Eleomas and Subcutaneous Lipoid Necrosis.**—Repetto reports a case of subcutaneous eleomas following subcutaneous injections of camphor in oil. The patient never had syphilis, tuberculosis or local pyogenous infection that could be considered predisposing factors for the development of the tumors. Because of the analogy that exists between subcutaneous lipoid necrosis and subcutaneous eleomas in their clinical evolution and histologic picture, the author believes that eleomas are a type of subcutaneous lipoid necrosis. The oil may act in these cases as a local traumatic factor that favors the development of the tumors, which is due to endocrine disturbances. In the author's case the evolution of the tumors was intensified during

menstruation. This fact in an obese patient indicated a possible relation between the endocrine disturbances, especially ovarian and thyroid disorders in his case, and the development of the subcutaneous lipoid tumors.

**Rational Treatment of Pernicious Anemia.**—Henning and Keilhack point out that the usual liver and stomach therapy has some disadvantages. If liver is given constantly, the patients develop an aversion to its taste, and the same applies to the liver and stomach preparations. The injection treatment is likewise unsuitable for permanent treatment. The chief aims that are to be realized in the continuous treatment of pernicious anemia is that the treatment is not too expensive, that it can be carried out by oral medication and that no aversion develops in case of continued use. In order to realize these aims the authors made further studies on Castle's intrinsic and extrinsic factors. The fact that the intrinsic factor is produced by the glands of the antrum permitted a considerable reduction in the quantity of stomach extract that is necessary for effective treatment. Instead of giving from 30 to 50 Gm. of stomach extract, they found that 5 Gm. of a powder prepared from the mucous membrane of the antrum was sufficient when it was combined with the necessary amount of extrinsic factor. It was also determined that the extrinsic factor does not have to be meat but may be vegetable protein. A preparation that combines the intrinsic factor in the form of antrum extract and the extrinsic factor in the form of vegetable protein was found effective in nine cases of pernicious anemia. Control tests indicated that only the combination of these two substances acts in the manner indicated by Castle's theory. The small amount of organ extract practically eliminates the problem of a possible aversion of the patient toward the treatment.

**Differential Diagnosis of Epilepsy.**—Moeller cites methods that have been tried to differentiate the types of convulsions occurring in children. She employed the hyperventilation method, injection of solution of posterior pituitary and alkalization (by means of potassium sodium citrate, until an alkaline reaction of the urine had been obtained). She resorted to these methods in 121 children who had attacks of convulsions. In seventy-eight of these children none of the three methods elicited convulsions. Some of these children were not subject to attacks in the course of their stay at the clinic, but the anamnesis disclosed that they had had convulsions, whereas in others the convulsions were sequels of encephalitis or were caused by a toxic hydrocephalus, cerebral tumor or cerebral deformities. In eight of the remaining forty-three children, salaam convulsions occurred. In five of these eight children it proved possible to elicit the typical salaam attacks by means of injection of solution of posterior pituitary. Hyperventilation and alkalization were not tried in these children. Of fifteen children with pyknolepsy, fourteen developed pyknoleptic attacks following hyperventilation. Injection of solution of posterior pituitary as well as alkalization always gave negative results in this group of patients. However, alkalization elicited or increased the convulsive attacks in nine out of twenty children with genuine epilepsy; in six others the result was doubtful and in the remaining five entirely negative. The author con-

cludes that by means of one of the three tests (injection of solution of posterior pituitary, hyperventilation and alkalization) it will be possible to determine the nature of convulsions in many cases.

**Diagnosis of Aortic Disorders.**—Ude points out that formerly the diagnosis of aortic sclerosis was based on such signs as the character of the second aortic sound, the amplitude of the blood pressure and the roentgenologic aspects. Later, various methods were devised to determine the volume elasticity. These were based on studies in which the mutual dependence of the factors controlling the circulation was mathematically formulated. Since most of the latter methods require considerable time, the author devised a simpler method which, although it does not give definite figures, nevertheless indicates the presence of changes in the aortic wall. He points out that the speed of the pulse wave passing along the aortic tube depends on two factors, the pressure in the arterial system and the elasticity of the arterial wall. The pulse wave that originates in the heart reaches sites where it can be measured; namely, at the right wrist and at the femoral artery in the flexure of the groin. These pulse waves have in common only the short section to the branching off of the innominate artery. If vascular changes exist on the way from the aorta to the groin, but not on the way to the radial, there must be a difference in time of arrival of the pulse wave at the wrist and in the groin. Since blood pressure changes practically have the same effect throughout the system, they do not influence the time difference in the arrival of the pulse waves. However, isolated changes in the aorta can be detected in this manner. Cases in which there is sclerosis of the arteries of the arm must of course be excluded. These sclerotic changes can be detected by palpation. Another important factor for a comparison of the time of arrival of the pulse wave at the wrist and in the groin is a constant ratio in the length of the two arterial tracts. In normally proportioned subjects this is always the case, and others must be excluded from this test. The author determined the time difference in the arrival of the pulse wave at the right wrist and in the groin on healthy persons and on patients with various defects of the aorta (aortic sclerosis and syphilitic aortitis). A tabular report of the results indicates how clearly changes in the aortic wall manifest themselves by a time difference. Aortitis and sclerosis show the same behavior, which is understandable when it is considered that in both cases the elasticity of the aortic wall is impaired. Independence from the blood pressure was proved by control tests.

**Increase of Blood Pressure in Adrenal Stimulation.**—Kuré and his associates point out that, whereas some investigators observed a hyperadrenalemia in essential hypertension, others denied it, and that it has been repeatedly determined that atropine exerts a favorable influence on hypertension. These and other problems induced the authors to investigate the reliability of the method used for the determination of adrenalemia, the relation between increased blood pressure in case of adrenal stimulation and hyperadrenalemia and finally the influence of atropine on hypertension. The results of their investigations indicate that the method, which had been employed for the determination of hyperadrenalemia, is sufficiently exact. They found further that the stimulation of the splanchnic nerve, particularly of its spinal parasympathetic fibers, always produces a noticeable increase in the blood pressure and hyperadrenalemia. Increase in blood pressure and hyperadrenalemia usually run parallel, but occasionally they differ considerably. The increase in blood pressure may be considerable in the case of slight hyperadrenalemia and vice versa. The stimu-

lation of the splanchnic terminations in the adrenals produced similar results. It appears that the increased blood pressure in the presence of slight hyperadrenalemia is due to a functional disturbance of the adrenals. The authors cite explanations that have been given by other investigators and also describe some of their own observations, and suggest that the adrenals eliminate a blood pressure increasing substance, which does not produce an epinephrine reaction with the method that was used for these tests. They assume that in certain cases the adrenals secrete a substance that exerts a stronger effect on its own vessels than on the vessels of the ear of the rabbit, or that it acts on other incretory glands and only secondarily on the vessels. Whether this substance originates in the cortex or in the medulla of the adrenals is still unknown. To be sure, these observations do not prove that every essential hypertension is caused by a hyperfunction of the adrenals. It was determined further that atropine has a paralyzing effect on the splanchnic terminations and thus inhibits blood pressure.

**Endo-Urethral Electrotomy for Prostatic Hypertrophy.**—Wildegans says that the endo-urethral punch methods (Young, Caulk) are not in use in Germany, but that McCarthy's method of electrotomy is employed. It is performed either with McCarthy's electrotome or with the instrument of Heynemann-von Lichtenberg. He emphasizes that electrotomy is not an intervention that can be done without preparation, but he stresses that it requires the same preparation as does a prostatectomy. He considers unsuitable for electrotomy all patients with advanced intoxication by urivable substances. Moreover, a vesical fistula should, if possible, be avoided prior to electrotomy. The possibility of free movement of the instrument in the posterior urethra and good vision are essential. The author regards as unsuitable for resection patients who always have hemorrhages in the course of the introduction of the cysto-urethroscope. It is also important that the urinary tract is free from severe infection. Advanced cystopyelitis-nephritis and infections in the region of the prostate and of the seminal vesicles contraindicate endo-urethral treatment. The author regards the isolated hypertrophies of the median lobe and the rarer pedicled adenomas at the neck of the bladder as best suited for the electrotomy. He says that the intervention should be more canalizing than excavating and he thinks that the selection of the correct sites for resection is more important than the mass of the resected tissue. The opinion of McCarthy and Davis that the endo-urethral method is applicable in 90 per cent of prostatic changes is not shared by the author. He points out that, because it is only a palliative method and does not promise anatomic cure, the endo-urethral therapy cannot replace the radical operation. He thinks that a final evaluation of the endo-urethral electrotomy is not possible as yet, but he regards it nevertheless as a considerable advancement in the treatment of hypertrophy of the prostate.

**Diagnostic Value of Sternal Puncture.**—Schulten demonstrates that the examination of a specimen of bone marrow which has been obtained by sternal puncture does not clarify all obscure hematologic cases. For instance, in chronic myeloid leukemia the bone marrow specimen withdrawn by sternal puncture usually provides but little information. To be sure, the number of myeloblasts and of premyelocytes is usually increased, but it is often difficult to determine how many come from the admixed blood. Moreover, the cases with large numbers of leukocytes usually cause no diagnostic difficulties, but even the subleukemic and the aleukemic myeloses can be detected quite readily by a thorough examination of the blood. If myeloblastic leukemias are accompanied by greatly increased

leukocyte values, their recognition is not difficult, except that there may be doubts whether a lymphatic or a myeloblastic leukemia exists. Clinical and hematologic signs, however, usually will permit a differentiation. The situation is entirely different if the leukemia is temporarily or permanently aleukemic. In these cases, sternal puncture may be of considerable diagnostic help. Other conditions in which sternal puncture may be of value are the lymphatic and myeloblastic leukemias and multiple myeloma.

**Test for Pancreatic Function.**—Berger and his associates describe a method which makes possible the determination of the action of the pancreatic ferment in the duodenal contents. The procedure is a functional test and is suited for studies on the physiologic and pathologic aspects of the external secretion of the pancreas. The duodenal contents are withdrawn by means of a tube at short intervals (every five minutes or, if the flow of the juice is profuse, every two or three minutes). This fractional withdrawal is continued for several hours. It is done while the patient is fasting, as well as after an oil tolerance test. The authors show that the exactness of this method surpasses that of other functional tests of the pancreas. It discloses disturbances of the pancreas (hypofunction as well as hyperfunction), which could not be detected by other methods. Moreover, by the use of the oil stimulus it makes possible the examination of the function of the gallbladder. This is important in view of the frequent concurrence of diseases of the biliary tract and the pancreas. The method makes possible at the same time the macroscopic, microscopic and bacteriologic examination of the pancreatic juice, the vesical and hepatic bile and the duodenal juice in their mixtures in the duodenum. The prolonged fractional withdrawal is less trying for the patients than may be assumed on first sight, but the efforts involved in the examination are considerable. The authors concede that the method still has defects, but they think that some of them can be eliminated. Nevertheless, they maintain that even in its present form the method has great value.

**Subfebrile Temperatures.**—Lauda designates as subfebrile temperatures slight increases in the body temperature which usually persist for long periods. He stresses that, whereas in some cases they differ from true fever only in degree, in other cases they differ from it in the essentials. In the presence of kryptogenic subfebrile temperatures, the first thought is usually of an infectious toxic process, quite often of tuberculosis, but other mitigated chronic inflammatory and septic processes are taken into consideration (tonsillitis, sinusitis, bronchitis, cystitis, pyelitis and so on). Moreover, febrile diseases, such as *Brucella* abortus infection and lymphogranuloma, may cause subfebrile temperature, and obscure neoplasms, such as hypernephroma, must be thought of. The author calls attention to protracted periods of increased temperature after febrile diseases, particularly after influenza. The protracted subfebrile temperatures after infectious diseases are most frequent in patients with an unstable sympathetic nervous system. These types of persons are also occasionally subject to a hyperthermia that is not a postinfectious condition. They are free from any pathologic condition that might result in increased temperature; the subfebrility is merely one of several signs of nervousness. These persons usually are characterized by vasolability, by rapid

changes from reddening to pallor and from a sensation of heat to chills, and by cold extremities, dermatographism, profuse sweating, tachycardia, tremors and diarrhea. Their moods are unstable and they are irritable and subject to depression. The increased temperatures may persist for months and even for years, but they may also disappear for a while and then return again. The definite diagnosis of the increased temperatures that are the manifestation of an unstable sympathetic nervous system may cause considerable difficulties. It may prove difficult to differentiate this condition from hyperthyroidism and tuberculosis. The author thinks that, on the whole, tuberculosis is diagnosed too often merely on the basis of increased temperatures and, as a result, many persons are sent to sanatoriums and subjected to treatment when they do not need it.

**Glutamic Acid as Substitute for Sodium Chloride.**—Mainzer directs attention to the efforts that have been made to find a substitute for table salt. It was the chief aim to replace the chlorine ion by a harmless ion that would have approximately the same seasoning effect. Several salt substitutes were prepared in which the chlorine ion was replaced, but the replacement of the equally objectionable sodium ion was not at all or only partly realized. The author cites factors which indicate that the disturbance in the renal function is highly important for the elimination of the sodium, chlorine and bicarbonate ions. He searched for a "salt substitute" that would meet the following requirements: 1. It should have the capacity to season. 2. It should resist meteorological conditions, particularly the dampness of the air. 3. It should be harmless for the organism. 4. It should be free from inorganic ions that tax the kidney. 5. It should be eliminated in a form readily managed by the kidney. He thinks that glutamic acid fulfils these requirements. After giving the chemical structure and describing the physical characteristics of the acid and its neutral salts, he says that animal experiments revealed that it causes no pathologic changes in kidney, urine or blood pressure. The monosodium salt has a strong seasoning effect (seven times stronger than sodium chloride) and is widely used for seasoning purposes in China and Japan. However, for the diet of patients with renal disease the author recommends the free *D*-glutamic acid rather than its sodium salt, because it is desirable to eliminate the sodium ion. To be sure, the seasoning capacity of the acid is considerably less than that of the sodium salt, but the quality of the taste is the same. The author is convinced that glutamic acid will exert no unfavorable influence on the renal function, but it will be necessary to examine whether it has an indirect influence on the elimination of other substances.

Diseases of Rectum. W. Zweig.—p. 466.

**Treatment of Idiopathic Dilatation of Esophagus.**—Heyrovsky says that so-called idiopathic dilatation of the esophagus has been designated also as chronic cardiospasm, spasmogenic dilatation of the esophagus, mega-esophagus, achalasia and so on. These various terms are applied to a disorder in which dilatation and lengthening of the esophagus results

from a functional inhibition of the passage of food through the cardia. The author is convinced that only dilation of the cardia or a surgical intervention can effect a cure and he says that in milder cases dilation of the cardia from the opened stomach according to von Mikulicz or cardiomyotomy according to Heller is advisable. As a third intervention for cases of diffuse dilatation of the esophagus he mentions a method of cardioplasty in which Marwedel and Wendel utilized the principle of the Heineke-Mikulicz operation for pylorostenosis. After citing figures regarding the efficacy of these methods, he points out that he himself resorted to an anastomosis between the abdominal portion of the esophagus and the fundus portion of the stomach. He exposes the cardia, mobilizes the lengthened and dilated esophagus, draws it into the abdominal cavity and anastomoses it with the stomach. He performed two esophagogastrostomies about twenty-five years ago, in both of which the conditions were favorable for subphrenic anastomosis. Roentgenologic controls after more than ten years disclosed that the dilatation of the esophagus had completely disappeared. Later this anastomosis was done in a greater number of cases, either by the abdominal or by the transpleural approach. The evaluation of the results obtained by himself and others convinced the author that subphrenic esophagogastrostomy is the best method for severe cases.

**Inhibition of Menstruation by Estrogenic Substance.**—Zondek found that the normal menstrual cycle can be influenced by the administration of estrogenic substance, in that the menstruation is postponed. To produce this result it is necessary to administer at least 70,000 mouse units, but if 200,000 or 300,000 mouse units is given the result is more certain; that is, at least one third of the quantity of substance necessary for the proliferation of the uterine mucosa must be administered to produce amenorrhea. The earlier the administration is begun (best immediately after menstruation) the more certain is the action. The duration of the resulting amenorrhea is not in proportion to the dose. The menstruation is retarded by from six to seventy days. Estrogenic substance can inhibit or entirely prevent the premenstrual proliferation of the uterine mucosa. If estrogenic substance (at least 200,000 mouse units) is given at the premenstrual phase, the further proliferation of the uterine mucosa is retarded. Estrogenic substance inhibits also the development of the corpus luteum, so that a parenchymatous degeneration and shrinkage may be the result. The gonadotropic hormones of the anterior lobe of the hypophysis are involved in the mechanism of the inhibition (perhaps shift in the proportion of follicle stimulating to luteinizing factor). This is indicated by the increased elimination of the follicle stimulating factor in the amenorrhea produced by the administration of estrogenic substance. The author emphasizes that menstruation is a complex hormone process in which the gonadotropic hormones of the anterior hypophysis as well as the ovarian hormones play a part. He thinks that the production of amenorrhea by estrogenic substance is of clinical value.

- Differential Diagnostic Value of Percussion of Pathologic Aorta. N. G. Edelman and V. N. Panov.—p. 292.
- Nanthosis. D. A. Kogan.—p. 294.

**Ammonium Chloride Therapy of Edema.**—Kanfor found that edema which proved resistant to the usual therapy rapidly disappeared on administration of ammonium chloride (from 8 to 10 Gm. daily) in a number of cases of chronic nephritis or nephrosis. He obtained the same striking diuretic effect with disappearance of anasarca in circulatory failure due to cardiac insufficiency. This was accompanied by a fall in the blood pressure and a slowing of the pulse. In some of his cases the effectiveness of both digitalis and ammonium chloride was only temporary. In such cases he found that alternating the digitalis therapy with that of ammonium chloride became again an effective means of producing diuresis. He likewise had cases in which the administration of ammonium chloride actu-

ally aggravated the anasarca and the patient's condition. He feels that ammonium chloride therapy is advisable in those cardiac cases in which digitalis has been ineffective and that when the two have lost their effect they should be alternated. Because of its diuretic effect, ammonium chloride can be administered without preliminary digitalization. The author found that the diuresis provoked by ammonium chloride was regularly accompanied by an increase in the urinary excretion of chlorides. This was not noted with regard to the urea excretion. The determination of the carbon dioxide tension of the alveolar air and of the ammonia excretion in the urine enabled him to evaluate the acid-base balance and the degree of the developing acidosis. Since the acidosis resulting from the administration of ammonium chloride did not always produce diuresis but in some of the cases actually aggravated the condition, he concludes that acidosis is not the determining factor in the mechanism of diuresis caused by this drug. The fact that excretion of the chlorides in the urine was in excess of that administered in cases of increased diuresis suggests that dissociation of the ions of ammonium chloride leads to their combination with sodium ions and that the excretion of the latter from the organism initiates the mobilization of the retained tissue fluids.

**Functional Cardiac Murmurs.**—Bystritskiy divides functional murmurs into "muscular" murmurs, which are associated with some disturbance of myocardial function of contraction and tonicity, and "accidental" murmurs due to a variety of causes but not related to myocardial function. The muscular functional murmurs are heard best at the apex, while the accidental murmurs are heard best at the base of the heart at the mouth of the large vessels where they originate. The muscular is a delicate blowing murmur, which is heard better when the patient is lying down. It is characterized by its inconstancy and disappears or at least diminishes in intensity but is never intensified on exercise. The first heart tone may be weakened or in part be replaced by the murmur, but it does not disappear. The area of radiation is smaller than with organic murmurs. It never extends beyond the left parasternal line and is thus limited to the space between that line and the left border of the heart. The author investigated the state of myocardial function in 583 cases of functional murmurs heard at the apex and demonstrated the presence of disturbance of myocardial function in 82 per cent. In a group of cases in which the murmur was heard at the base, myocardial function was disturbed in only 12 per cent. The author points to the well known frequency of functional murmurs in pregnancy. Their mechanism was variously ascribed to the increase in the blood volume and the amplitude of the systole, the acceleration of the blood stream, the lifting of the diaphragm, and only exceptionally to toxic lesions of the myocardium. He found in his study of 230 pregnant women that the functional murmurs were almost always localized at the base. He concludes that these are accidental murmurs not related to the myocardium and that recognition of muscular functional murmurs is of diagnostic value because, besides the ruling out of an organic valvular lesion, it points to disturbance of myocardial function. The value of accidental murmurs to the cardiologist is questionable because of the multiplicity of conditions that can cause it.

**Tularemia—Disease of Lemmings.**—Sylvest says that the fact that lemmings (*Myodes lemmus*) in their migrations in great numbers at certain times are attacked by infectious disease and die and that simultaneous diseases occur in man has been known in Norway for centuries. Lemming fever was reported in 1532 by Jacob Ziegler, and Ole Woem's description (*Historia Animalis*, 1653) has now been verified as to both the clinical picture and the source of infection. Tularemia and the disease of lemmings are believed to be identical.

## SOME OF THE PREVENTIVE ASPECTS OF THE MENTAL HEALTH PROBLEM

CHAIRMAN'S ADDRESS

HORTON R. CASPARIS, M.D.  
NASHVILLE, TENN.

During the past two or three decades, as modern psychiatry has been developed in this country under the leadership of Dr. Adolf Meyer, there has gradually appeared a broader and broader realization of the importance of mental health. The differentiation of functional mental disorders from organic mental disorders, the improved facilities in medical schools for teaching psychiatry, the training of private practitioners and the establishment of clinics and institutions for carrying out the improved methods of diagnosis and treatment have all contributed to a wide stimulation of interest in the subject of mental health. Also, these developments have brought a better understanding of the whole problem and have indicated its immensity. For example it is said that the majority of the hospital beds in the United States are occupied by individuals who are there because of mental disorders. This is rather appalling, especially if we pause and recall how many there are of us who are still ambulatory.

With this huge problem before us and with the rather wide recognition of its importance it seems that the time is ripe to begin to direct more attention toward the preventive aspects of poor mental health than we have in the past. It is not meant by this that psychiatrists have not been actively concerned with prevention, but the incidence of mental disease is so great that they have been more or less swamped with mental problems already developed. In that they have attempted to prevent less serious problems from becoming more serious ones, of course they have practiced prevention in the broader sense. Even a further step in the direction of prevention has been made chiefly by the psychiatrists, and that is that mental hygiene and child guidance clinics have been established. However, the attendance at these clinics is made up almost entirely of children who already have well developed problem difficulties. My purpose then in this discussion is to emphasize the importance of beginning preventive work before mental problems develop, to try to point out how it can be done, and to indicate where the chief responsibility for its accomplishment lies.

But, before proceeding directly into the discussion of prevention, it might be well to recall that there has been a great deal of criticism by the medical profession

directed at certain trends in mental health work. Since almost every adult considers himself thoroughly capable of training children along ideal lines, and since the medical profession has to a large extent failed to assume the responsibility for giving information concerning this important procedure, quite naturally a number of individuals, even though inadequately trained, have entered this field. Some have gone in because of sentimental reasons. There are others who have been cheated out of the opportunity to train children and find in the child guidance clinic an opportunity for personal satisfaction and heavenly contentment. The foregoing is offered as an explanation for some of the critical remarks from the medical profession and is in no sense meant as a criticism of the well trained workers in this field whose accomplishments are commendable. We medical men like others have some tendency to criticize those who take over our responsibilities, even if we make little effort to assume them ourselves; but on our side we should not be blamed too severely for not taking over this work, since the medical schools have been at fault in not teaching us adequately concerning the various aspects of mental health work, especially the preventive aspects.

The realization that mental health is quite as important as physical health, that the two are undissociable and together concern the everyday activity of the whole human being, is gradually taking root. It is further being realized, since the two are equally important and undissociable, that the individual potentially best qualified to assume the responsibility for the health of this whole human being is the physician himself. If prevention is going to play the important rôle in mental health that it has in physical health, and there is no reason why it should not, we should begin practicing preventive measures as near the beginning as possible, since we have found that that early start is so effective in the prevention of poor physical health. It therefore follows that those who are going to be chiefly concerned with these activities are the pediatricians and other physicians who have the opportunity to supervise the care of the child from the beginning.

Let us return now to some of the practical aspects of prevention. If we begin by using the familiar term "health" instead of "hygiene," when thinking of mental functions, which places mental health on the same plane as physical health, and if we think of a human being in action in terms of behavior rather than in terms of mentality, I think we might be able to wean ourselves from much of the confusion that exists or has been created. If we eliminate the word "normal" and substitute the word "adequate," I think we shall be on much firmer foundation. And, if we will only recall that there are certain familiar common sense laws and principles which have guided human beings to and through an adequate existence ever since there have been human beings; that these simple basic laws have

Read before the Section on Pediatrics at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

never changed and never will change; that we may group them under the head of religion, philosophy of life, common sense, or what you will, then shall we realize that any and all of us are capable of taking part in this work.

Going a step further, the task will be simpler if we recall that there is no fundamental difference mentally between human beings at any age. Infants differ from adults only in that adults through experience have learned to behave differently from children. In other words, child psychology is nothing more or less than human psychology. Psychology is that branch of science which concerns itself with the study of the mind or mental reactions. Mental reactions constitute our behavior. Behavior is the manner in which all of us spend our time, and all of us, regardless of age, spend all our time trying to get what we want (or that which produces comfort and pleasure), and trying to avoid what we do not want (or that which produces discomfort and displeasure).

Beginning then with the new-born infant, let us see if we cannot indicate briefly how adequate human beings are built. In the first place, the building material varies. In other words, no two infants start with the same hook-up, endowment or inheritance. We do not have to know immediately what the quality of this material is, since we are familiar with the plan of building. We must, however, recognize as nearly as possible as we go along whether we are getting the best out of our building material, and also that we are not trying to build a stronger mental structure than the material permits. The load must not be unbearable. The recognition then that the initial material out of which we try to build adequately functioning human beings varies tremendously in quality is about all we can do about inheritance.

With regard to environment, we first and continually consider our material and, as already outlined, build as well as we can with that particular material. To do this we must pay as careful attention to mental nutrition as we do to physical nutrition, for unless human beings are mentally well nourished we cannot expect them to develop into adequately behaving human beings. Mental nutrition is made up largely of the satisfaction of accomplishment commensurate with one's ability to accomplish. If we at any stage push any one too long beyond his ability to accomplish, disaster follows. Apply this to almost any phase of activity in life and it will readily be seen where the root of much of our trouble lies. On the contrary, if one accomplishes more or less commensurate with one's ability to accomplish, we usually see in that individual a stimulation to go ahead, sustained morale, self respect and at least much of the make-up of ambition.

Another human quality which is one of our main stays in respect to adequacy is courage. What are some of the elements which we commonly recognize as components of courage? Of course some human beings are born with more of this quality than others, but we may say simply that life is made up of a rough and a smooth side, a pleasant and an unpleasant side. We are apt to call any individual who faces the rough side with his chin out as well as who enjoys the smooth side a courageous individual. How then may we train the child to be courageous? From the very beginning it is important that he recognize that there is the unpleasant as well as the pleasant. His reaction to the unpleasant from the beginning is apt to be crying. This is natural, since it is his only mode of expressing displeasure or

discomfort. Infants soon learn to enjoy affection, sympathy and attention just as all human beings do, and if when he cries these are bestowed on him he quickly learns to use crying to get them. If, on the other hand, when he cries these are withheld and only necessary attention is given calmly, and one holds back affection, sympathy and undue attention until he is pleasant and behaving nicely, he soon learns that this is the way to get these things. He thus adopts thi<sup>s</sup> method of accomplishment which he has found successful and he becomes a pleasant, attractive individual. Parents through their sentimentality and self indulgence find it difficult to carry out these practices, but if persisted in they will succeed in preventing a child from being a whining, crying, pouting and tantrum-throwing individual. In other words, he soon learns to face his difficulties more or less pleasantly and is called a brave or courageous child. Remember that we adults cry after our fashion just as children do if we have not learned to face our difficulties with equanimity. The only difference is that our crying does not usually sound the same as that of a child. Instead, we swear, complain and offer alibis for our failures. In brief, we can train children from the beginning to face the rough side of life as well as enjoy the smooth side and thereby save many older children and adults from many of their neurotic tendencies, nervous breakdowns and suicidal tendencies.

Time and space do not permit me to discuss in detail many of the phases of behavior which go to make up everyday conduct. It might be well, however, merely to mention the matter of the amount of energy healthy children have, since it plays such a prominent part in our attitude toward them. Too often in our care of children we try to smother their normal, wholesome energy simply because its intensity worries us adults. The healthy energy of a child may be compared with the familiar electrical energy. We do not dare try to stop electrical energy but we may direct it along wholesome lines and accomplish remarkable things. This applies to the energy of children. It is not meant by this that we do not say "no" to children, for we can always say "no" reasonably, fairly and honestly to a child and demand obedience when he is doing that which is dangerous to himself or others, when he is destructive of valuable things, when he is interfering with the rights of others, and when he is making any unreasonable demands. If time permitted to elaborate it would be seen that these same "noes" reasonably apply to adults also, except that adults are supposed to have reached the age of discretion and may do things that are dangerous to themselves without interference.

Further, children should be treated always as if they were older than they are, one should have confidence in them, even though they may make mistakes or not always do things as we think they should, for it should be remembered that we ourselves blundered along and some one was kind enough to encourage us and permit us to live in spite of our mistakes and failures. Encouragement should be given for worth-while accomplishments even though they appear quite insignificant. Worth-while accomplishments are those that are good commensurate with the child's ability to perform. Children should be made responsible members of the family according to their ability to assume responsibilities, even though small, and should never be thought of merely as attachments to the family who are there to be told what to do and what not to do. If there is only one child in a family of three he should get the impression

that he is only a third of the family, and the smallest third, rather than seven eighths of it. This is difficult, but important for his sake.

One could go further and explain the basis for lying, stealing, reliability, dependability and how to make children mind, through all the elements that go to make up our everyday behavior, but the point of this discussion is to try to emphasize that the indications and methods for constructing mentally adequate older human beings out of infants and children are specific and definite. Knowing what to do in any given situation is not difficult, for it is just what an adult would consider the fair procedure for himself under fundamentally similar circumstances. All answers should be based on the age-old simple common sense laws that are conducive to adequate human conduct. But getting it done is often extremely difficult, for varying degrees of sentiment interfere and too frequently distort our views and warp our decisions.

Finally, there is great need and even a rapidly increasing demand from laymen for information concerning the preventive aspects of the mental health problem, and it is the responsibility of those of us physicians who care for children from the beginning to prepare ourselves to give it. Psychiatrists should help teach us and are certainly indispensable in helping us solve the more serious problems. Medical schools must emphasize prevention in their teaching as well as teach diagnosis and treatment of mental disease. The mental health problem in all of its aspects, then, is our combined responsibility and is not the property of any particular group.

### PROGNOSIS IN GALLBLADDER SURGERY

WILLIAM D. WILSON, M.D.  
ROCHESTER, MINN.

EDWIN P. LEHMAN, M.D.

AND

WILLIAM H. GOODWIN, M.D.  
UNIVERSITY, VA.

Recognition of the deficiencies of gallbladder surgery from the point of view of complete relief of symptoms has troubled both surgeons and internists. It is generally agreed that, although the place of surgery in the treatment of a large group of patients with gallbladder disease is established, in another group the benefits of surgery are not so obvious. Many clinics have attempted to determine the criteria that place the individual patient in one or the other group. The method usually employed has been statistical in nature, consisting of analyses of clinical results as related to variations in history, physical examination and laboratory data.

Conclusions from current literature may be broadly generalized. Three criteria have received particular attention. Observers are in unanimous agreement that the patient with cholelithiasis has a better chance for relief of symptoms than the patient who has no stones. This contrast has been ascribed to the greater violence of symptoms in the former instance, either offering an opportunity for relatively greater relief of symptoms or affording a more accurate diagnosis. As a corollary it is felt that the more severe the symptoms the more probable the relief. The third contention is much less completely accepted and is the most widely discussed element in gallbladder surgery at present. The opinion

is apparently gaining ground that the nearer the time of operation to the onset of the acute attack, the better the prognosis for operative recovery and symptomatic cure.

The present paper consists of an analysis of 610 consecutive cases of cholecystitis and cholelithiasis studied along conventional lines. In addition an attempt has been made to assay the significance of results by the use of statistical formulas. The final aim in the analysis has been to throw light on criteria that may offer a prognosis in the individual case.

#### MATERIAL

The 610 cases of gallbladder disease were treated at the University of Virginia Hospital by operation at the hands of twenty surgeons during the years 1921 to 1934. Twenty-two of the patients died in the hospital, a mortality rate of 3.6 per cent as compared to a rate of 5.8 per cent in 512 cases reported from this hospital in 1921 by Goodwin.<sup>1</sup> Cases of carcinoma in or near the gallbladder are not included.

Written replies to a questionnaire or visits to the clinic afforded an estimate of final results in 447 cases (76 per cent) at intervals following treatment of from four months to thirteen years. The patients were questioned concerning (1) general health, (2) recurrence of symptoms, (3) food tolerance, (4) hernia, (5) capacity for work and (6) their estimate of the effects of treatment. These replies were first graded as follows:

**GRADE 1. Excellent Result.**—General health good; no recurrence of symptoms; no diet idiosyncrasy; no hernia or weakness of the operative wound; patient able to do ordinary work. The patients ascribe their freedom from symptoms to the operation.

**GRADE 2. Good Result.**—General health good; mild digestive symptoms or a few foods not well tolerated; no hernia; patient able to do ordinary work. The patients ascribe their great improvement to operation.

**GRADE 3. Fair Result.**—General health fair; bothersome digestive symptoms or occasional pain in the right upper quadrant; no hernia; patient usually able to do ordinary work. The patients believe themselves improved by operation. Many of the patients in this group are in fact but slightly discomforted by their symptoms and none are incapacitated.

**GRADE 4. Poor Result.**—General health poor, colic or frequent and marked indigestion; hernia; unable to do ordinary work. The patients consider themselves unimproved or made worse by operation. It must be noted that patients are placed in this group who present one of the unfavorable manifestations, although a few had several of them.

For simplification, the cases in groups 1 (excellent) and 2 (good), together with cases in which deaths were reported from other causes and in which there was no recurrence of gallbladder symptoms, are grouped together as "satisfactory results." The cases in groups 3 and 4, together with the deaths from any cause in which a recurrence of gallbladder symptoms had been reported, are grouped as "unsatisfactory results." This simple grouping definitely tends to minimize the value of surgery in gallbladder disease, since many patients in group 3 were well satisfied with the outcome of treatment. The really bad results are few in number. If one was to combine groups 1, 2 and 3 as "satisfactory results," a grouping for which there would be some justification, the percentage of satisfactory results would be 91.3 per cent as compared to 74.3 per cent in the present grouping.

1. Goodwin, W. H.: The Surgery of the Gallbladder, with an Analysis of Five Hundred and Twelve Cases, South. M. J. 15:712 (Sept.) 1922.

## METHODS OF ANALYSIS

The data have been analyzed by the usual comparisons of percentages. Age, sex, race, duration and severity of symptoms, presence or absence of jaundice, presence or absence of a history of colic, presence or absence of gallstones, the degree of functional disturbance indicated by the cholecystogram, the pathologic stage of the disease (acute or chronic), and the type of operation have been studied with reference to the hospital mortality and the final symptomatic result. An additional factor studied has been the degree of pathologic change in the diseased gallbladder, an approach which has not previously been emphasized. The correlation between cholecystographic diagnosis and pathologic changes has also been studied.

The data have been subjected to statistical validation to define the significance of the results. The reason for such an attempt is obvious. Practical conclusions are commonly drawn from the percentage analysis of clinical material, based on samples so small or percentage differences so slight that the conclusions must be suspect. It has been deemed desirable not to add another such analysis without at least attempting to show whether the presented data have or have not statistical significance.

The method employed has been that involving the use of the "chi-square distribution."<sup>2</sup> This method furnishes an estimate of the significance of compared figures, taking into consideration the size of the samples from which they are derived. The mathematical end-point expressing such determinations of significance is a quantity designated *P*, which may be roughly described as indicating to what degree the element of pure chance has been influential in the results. Any data for which the calculated *P* is 0.01 or less may be considered significant. If *P* lies between 0.02 and 0.05, conclusions from data are probably significant. If greater than 0.05, the differences may be due to chance alone. The application of this method to the statistical studies here presented is indicated in the tables, in which both the value of *P* and the presence or absence of significance of the results are given. In the case of the statistical data referred to in the text alone and not presented in tabular form, the analysis revealed statistical validity in no instance.

The data are grouped under four heads: clinical, cholecystographic, pathologic and operative. They are presented without immediate reference to statistical evaluation, which is reserved for discussion later.

## CLINICAL DATA

*Age.*—Judd and Priestley<sup>3</sup> demonstrated better results in the older patients undergoing cholecystectomy and cholecystostomy. The present study revealed an apparent tendency toward better ultimate results with increasing age from 21 to 60 years.

*Sex.*—In the entire series there were 517 females and ninety-three males, a ratio of 5.5 to 1. The results were satisfactory in 71.2 per cent of the males and 74.8 per cent of the females.

*Race.*—An approximately equal percentage of satisfactory results are observed in the white and Negro races (74.4 per cent in the former and 72.2 per cent in the latter). The operative mortality rate in the white race (540 cases) was 4.1 per cent, while in the Negro race there was no death in seventy cases.

*Duration of Symptoms.*—Study of the duration of symptoms of gallbladder disease before operation presents nothing conclusive. There is no apparent trend toward better ultimate results from operation with a history of symptoms of longer duration. An exceptionally high operative mortality (9.6 per cent) in the group of patients who had had symptoms from one week to one month before operation was noted.

*Severity of Symptoms.*—The final results in patients having had mild symptoms preoperatively are only slightly less satisfactory than in those in whom the symptoms had been severe. This unexpected finding can be explained only on the basis of the personal equation, here doubly operative first through the original recorder of the history and secondly through the collator of the material. There is an expected difference in operative mortality (4.5 per cent in the cases presenting severe symptoms as against 0.6 per cent in those presenting mild symptoms).

*Jaundice and Colic.*—Study of the ultimate results with relation to the presence or absence of definite jaundice and colic offers no positive conclusion. The percentage of satisfactory results in those cases without a definite history of colic is actually slightly higher than in those with a history of colic. These results are definitely contradictory to the usual observations recorded.<sup>4</sup> They also present the same discrepancy that was found in studying the severity of symptoms. Probably the same explanation must be given.

## CHOLECYSTOGRAPHIC DATA

Numerous authors have compared the cholecystogram with the pathologic change found at operation. Brooks<sup>5</sup> concluded that "careful application of the method gives results on which the anatomical pathological change in the gallbladder may be estimated." Rose,<sup>6</sup> in a composite study of 6,268 cases reported by twenty authors, found that gallbladders diagnosed as abnormal by cholecystogram were pathologic in 93.3 per cent of cases. Case<sup>7</sup> stressed the point that cases of cholelithiasis examined by cholecystogram are almost certain to show either "no shadow" or "stone positive," or both, and found that both of these criteria were lacking in only 4.3 per cent of his cases. Ferguson and Palmer<sup>8</sup> found that cholecystographic diagnosis, when considered with clinical history, was pathologically correct in 90 per cent of cases.

In this series 252 cases were submitted to cholecystographic examination before operation. A comparison between the degree of functional disturbance as indicated by the x-rays and the symptomatic results reveals no marked differences in favor of the cases that presented marked x-ray evidence of gallbladder disease.

It might be noted in passing that, although the number of cases is small (fourteen), the ultimate results in cases of normal cholecystographic shadow are only 50 per cent satisfactory. This is of particular interest not only in the use of the normal cholecystogram as a warning against operation but also to point further the suggestion of Graham and Mackey<sup>9</sup> that a proportion of unsatisfactory results in gallbladder surgery arises from mistaken diagnosis.

## PATHOLOGIC DATA

Although it may be acknowledged that the estimate of the actual degree of pathologic change in the gallbladder wall is conditioned by a large personal equation, it is worth while to attempt to correlate the clinical results with this variable. After all, the duration of symptoms, the severity of symptoms, the presence or absence of colic and jaundice, and the changes in the

TABLE 1—*The Presence or Absence of Cholelithiasis and Results\**

	Cases	Hospital Mortality	Follow Up	Symptomatic Results	
				Satisfactory	Unsatisfactory
Stone present	421	15 3.5%	308	243 79.0%	65 21.0%
Stone absent. . .	187	7 3.7%	139	89 64.0%	50 36.0%
Total	610	22	447	332	115

\* Statistical evaluation applied to operative mortality  $P = 0.91$  not significant. Statistical evaluation applied to symptomatic results  $P = 0.01$ —; significant.

cholecystographic shadow stem ultimately in most cases from anatomic alterations. This correlation has not often been emphasized. Weir and Snell<sup>10</sup> may be quoted as follows: "Permanent good results are obtained in from 80 to 95 per cent of cases in which stones are present, and in noncalculous disease of the gallbladder comparable results are obtained when the pathologic process is advanced" (italics ours).

The degree of pathologic change in the gallbladder wall has been classified as "mild," "moderate" or "marked." No definite limits between these grades can be specified. The mild degree of change represents slight fibrosis and minimal infiltration with inflammatory cells, a pathologic picture not far removed from the normal. The moderate degree represents definite thickening of the gallbladder wall and unmistakable infiltration, often associated with pericholecystic adhesions and enlargement of the cystic lymph gland. All other cases including most of the cases of acute cholecystitis are placed in the third group.

*Cholelithiasis Versus the Stoneless Gallbladder.*—Cases with and without cholelithiasis, including both the acute and the chronic cases, have been compared as to results (table 1). It is noted that the mortality rate is equal in the two groups but that there is considerable difference in the percentage of satisfactory results obtained in favor of the group presenting stones. This finding agrees with accepted opinion.

A comparison was made in cases of chronic cholecystitis alone between those with and those without stone. In the cases with stone the hospital mortality was only 0.8 per cent (228 cases) as contrasted with a mortality rate of 3.3 per cent (151 cases) in those without stone. These figures do not include cases presenting chronic cholecystitis and stone in the common duct, of which there were twenty-eight, with an operative mortality of 10.7 per cent. The significance of the difference between the first two mortality rates is not clear. It is possible that the cases of chronic cholecystitis without stone may represent those cases in which the diagnosis was wrong. The stoneless case is obviously less accurately diagnosed. The symptoms for

which operation was done in certain of the stoneless cases may have originated from coronary disease or some other condition unrelated to the disease of the gallbladder.<sup>9</sup>

*Degree of Pathologic Change.*—The comparison of symptomatic results as related to the degree of pathologic change and as related to the presence or absence of stone presents interesting data (table 2). In the stoneless group, the group with stone, and the combined group, the results are about 80 per cent satisfactory when a marked degree of pathologic change is found. It is suggested by these figures and by those presented in table 1 that about 80 per cent of satisfactory symptomatic results may be expected when either cholelithiasis or a marked degree of pathologic change is present.

Comparison between the radiographic measurement of gallbladder function and the degree of pathologic change reveals a close correlation when the total 252 cases submitted to cholecystography are considered (table 3C). As might be predicted, this correlation is also close in the cases complicated by stone (table 3A). On the other hand, in the stoneless group, although some tendency toward the same correlation is apparent (table 3B), it is not so close. These results

agree with the generally accepted conclusions in regard to the value of the cholecystogram used as an index of functional integrity of the gallbladder.

*Acute Versus Chronic.*—We have compared the results following operation in cases presenting pathologically acute gallbladders with the results in those cases which were not acute. It is apparent that there

<sup>10</sup> Weir, J. F., and Snell, A. M. Symptoms That Persist After Cholecystectomy. J. A. M. A 105:1093 (Oct 5) 1935

is often some lack of clarity in the use of the word "acute." The pathologically acute gallbladder is not always the clinically acute gallbladder. Not infrequently after the subsidence of fever, leukocytosis, increased pulse rate, pain and tenderness, operation will reveal a gallbladder the condition of which is pathologically that of acute inflammation. If a decision is to be reached on the desirability of early surgery in acute cholecystitis, observers must come to some uniformity in the definition of acute cholecystitis. It must

be specified as to whether the term is used to describe the clinical course or the pathologic picture. In the present instance we have confined the use of the word to the latter. The group of cases, therefore, classified as acute contains a proportion of cases in which acute symptoms have largely subsided. It must be remembered in this connection that what appears to be pus in the gallbladder has been said to be not necessarily a purulent exudate.<sup>11</sup>

This comparison between the acute cases, on the one hand, and the subacute and chronic, on the other hand, shows very slightly better results in the former group.

## OPERATIVE DATA

**Choice of Time for Operation in Acute Cases**—During the past twelve years there has been a gradual change of opinion with regard to the treatment of acute cholecystitis. Moynihan,<sup>12</sup> Lewis,<sup>13</sup> McGuire,<sup>14</sup> Deaver and Burden,<sup>15</sup> and Bruggeman<sup>16</sup> have earlier expressed themselves as in favor of nonoperative treatment of cholecystitis during the clinically acute stage, an exception being made when the patient under observation becomes definitely worse. As early as 1923, however, Walton<sup>17</sup> compared acute cholecystitis to acute appendicitis and advised immediate operation. This opinion was supported by the observation of Crile<sup>18</sup> showing a larger percentage of cures following cholecystectomy in the acute stage than in the chronic stage. Later

Mentzer,<sup>19</sup> Zinninger,<sup>20</sup> Graham,<sup>21</sup> Miller,<sup>22</sup> and Stone and Owings<sup>23</sup> expressed the opinion that early operative treatment is preferable to expectant treatment. Judd and Phillips,<sup>24</sup> as a result of a study of 508 cases of acute cholecystitis, concluded that early operation seems to be justified. Miller<sup>22</sup> found that the average length of time from the onset of acute symptoms to operation in fatal cases of acute cholecystitis was 15 days, and in those in which recovery occurred, 8.3 days.

In the present series the average interval between the onset of acute symptoms and operation was 11.1 days in fatal cases and 8.1 days in those in which recovery occurred. The operative mortality for the acute group was 4.7 per cent (seven cases). One patient died of peritonitis, three of pneumonia, one of empyema of the pleura, one of multiple liver abscesses and one of "circulatory collapse." Six instances of rupture of the gallbladder were found in 610 cases, operation being performed in one instance on the day of onset of acute symptoms. Other cases of rupture were discovered at

result with relation to the degree of clinical acuteness as measured by the time of operation following the onset of symptoms. If grouped by two-day intervals the number of cases in each group is too small to have significance and no regular variation in mortality is found with an increasing interval between onset of symptoms and operation.

If, however, we group the cases under the formula used by both Zininger<sup>20</sup> and Graham,<sup>21</sup> dividing the acute cases at the forty-eight hour period, the operative mortality is found to be zero in eleven cases in which operation was done within forty-eight hours after onset of symptoms as compared to an operative mortality of 5 per cent in 138 cases in which operation was done later (table 4A). This difference will be discussed later.

**Type of Operation.**—For the sake of completeness, the types of operation were compared in regard to the results. The best ultimate results were apparently obtained from combined cholecystectomy and choledochostomy. With the exception of three cases of choledochostomy alone, however, this group also carried the highest operative mortality (12.3 per cent of seventy-three cases). It is of interest to note that, of those patients who underwent choledochostomy with or without cholecystectomy, 8.7 per cent were reported by relatives as dead with a recurrence of symptoms, while of those undergoing simple cholecystectomy only 1.3 per cent of 518 patients had died with any recurrence of symptoms.

#### COMMENT

Since no statistically valid figures dealing with results are omitted from the accompanying tables, it will be seen that few of the data presented withstand the scrutiny of statistical evaluation. In spite of a fairly large number of cases, the great majority of comparisons recorded have no statistical significance. The application of this method with the same result to a number of tables published by other authors has cast doubt in our minds on much that has been accepted as proved on the basis of measured clinical results. Perhaps the value of the present contribution lies not only in the results themselves but also in pointing out what havoc may be wrought with percentage conclusions from clinical material when statistical validation of the data is attempted.

The only comparisons that statistical control shows to be significant between the criteria studied and the symptomatic results obtained are those dealing first with gallstones and secondly with the degree of pathologic change in the gallbladder wall. When gallstones are present, clinical results are 79 per cent satisfactory as compared to 64 per cent satisfactory when they are absent (table 1). When the pathologic change in the gallbladder wall is marked, the clinical results are 82.2 per cent satisfactory; when it is moderate, 76.6 per cent satisfactory, and when it is mild, only 57 per cent satisfactory (table 2C). These two results give weight to the conclusion rather generally expressed in present-day thought that the patient with a really diseased gallbladder has an excellent chance of a satisfactory symptomatic result if the gallbladder is removed.<sup>25</sup> The problem resolves itself into one of accurate diagnosis.

In this connection it is interesting that the correlation between the degree of pathologic change and the degree of deviation of the cholecystogram from the normal is statistically significant (table 3C). This finding offers

support to the general attitude of reliance on the cholecystogram as a diagnostic aid.

One of the correlations dealing with hospital mortality, although shown to have no statistical significance, deserves discussion. It has already been noted that in eleven cases of pathologically acute cholecystitis, in which operation was done within forty-eight hours after onset of symptoms, the mortality was 0 per cent, whereas in 138 patients operated on later the mortality was 5 per cent (table 4A). An obvious temptation is presented to draw conclusions that are shown by statistical evaluation to be not justified. In an attempt by increasing the size of the sample to bring corresponding comparisons within the realm of significance, we have subjected the combined figures of Graham,<sup>21</sup> Zininger<sup>20</sup> and our own to statistical inquiry (table 4). It is seen in this table that no one of the three series taken separately has statistical significance; nor has the summation of the three series, in spite of the fact that the mortality of cases in which operation was done more than forty-eight hours after onset of symptoms is almost three times that of cases in which operation was done earlier. In other words, it can be said that the desirability of early operation in acute cholecystitis has not been proved by these figures which base judgment on mortality rates.

#### SUMMARY

1. Analyses of a series of 610 consecutive cases of cholelithiasis and cholecystitis covering a period of thirteen years gives a hospital mortality rate of 3.6 per cent. The follow up of survivors includes 447 cases (76 per cent).

2. In addition to the usual percentage tabulation, the data are statistically controlled by the method of "chi-square distribution."

3. This method demonstrates in the present series no statistical significance in comparisons between the symptomatic results and such factors as age, sex, race, duration of symptoms, severity of symptoms, presence or absence of jaundice, presence or absence of a history of colic, the degree of functional disturbance indicated by the cholecystogram, the pathologic stage of the disease (acute or chronic) and the type of operation.

4. Following the application of statistical analysis to the data, these conclusions are justified:

(a) Cases of cholelithiasis present satisfactory clinical results in 79 per cent of cases; cases without stone, in 64 per cent.

(b) Cases that show a marked degree of pathologic alteration of the gallbladder wall present satisfactory clinical results in 82.2 per cent of cases; with a moderate degree of alteration, 76.6 per cent; with a mild degree, 57 per cent.

(c) The cholecystogram is a significant index of the degree of pathologic change in the gallbladder.

(d) The desirability of early operation in acute cholecystitis is not proved when measured by mortality rates.

---

**The Calcium Requirement.**—The amount of calcium needed in the normal maintenance nutrition of the human adult has been carefully investigated by means of large numbers of calcium-balance experiments made with healthy men and women. In the average of about 100 such experiments, it has been found that the body requires for mere maintenance, that is, in order that it shall not persistently lose calcium from its own tissues, 0.45 gram of calcium per day per 154 pounds of body weight.—Sherman, H. C.: *Food and Health*, New York, Macmillan Company, 1934.

## A STUDY OF DIABETES MELLITUS AMONG EX-SERVICE MEN

PHILIP B. MATZ, M.D.

Chief, Research Subdivision, Veterans' Administration  
WASHINGTON, D. C.

A study of diabetes mellitus similar to the present one was made in 1931 and included a clinical, laboratory and dietetic survey of a group of 300 diabetic veterans for the purpose of ascertaining whether the conditions found in the veteran population were comparable with those seen in civil life. The study showed that 13 per cent of the group first gave evidence of the diabetic disease during the period of military service at an average age of 32 years and that 87 per cent gave a history of the onset of the disease after discharge from the military service, at an average age of 37 years.

In the study referred to an effort was made to learn whether or not the traumas of warfare and certain neurogenic factors observed in the military service were in any way related to the inception of the diabetic condition. In addition, an inquiry was made to ascertain whether or not postwar social and economic hardships and maladaptations were in any way conducive to the diabetic state. The evidence in favor of the conditions enumerated as etiologic factors were not convincing. The inception of the disease could be better explained on the basis of constitutional predisposition, obesity, faulty metabolism, concomitant internal secretory disturbances and certain other individual factors.

### CLASSIFICATION

The present study includes 1,663 living diabetic veterans. These patients were grouped according to the classification of the diabetic condition as suggested by Joslin. The diagnostic data in each case were carefully reviewed and the patient was placed in a particular group only after he had met all the criteria required for that particular classification.

Table 1 shows that, of the total number of diabetic veterans, true diabetes mellitus was found in 88.6 per cent, potential diabetes in 8.9 per cent, unclassified diabetes mellitus in 1.7 per cent and renal glycosuria in 0.8 per cent.

In comparing these data with similar data of Joslin,<sup>1</sup> it is noted that the incidence of potential diabetes mellitus in Joslin's group is very much smaller than in the present study. The explanation is that the veterans are a younger group of men of an average age of 43 years. It is probable that many of the cases of potential diabetes mellitus will eventually be reclassified and found to be cases of true diabetes mellitus.

It is of interest to note that twenty-eight, or 1.7 per cent, of the group were found to have unclassified diabetes mellitus. This compares with 10 per cent of Joslin's group of 13,000 cases. It is possible that, as the veterans grow older and are subject to various diseases commonly associated with this type of diabetes, the incidence of unclassified diabetes mellitus will increase. In addition it was found that sixty-one cases of the total group gave evidence of some coexisting abnormality of one or more of the internal secretory

glands; however, it was decided that, in spite of this fact, the diabetic condition met the criteria established for true diabetes mellitus.

It is noted that the incidence of renal glycosuria in the present study is 0.8 per cent, as compared with 0.3 per cent in Joslin's group. Although the criteria of Joslin were applied in the present instance, it is nevertheless possible that, on further observation and study, certain of the patients will eventually be found to present evidence of potential or true diabetes mellitus.

### HEREDITARY AND FAMILIAL HISTORY

Baur, Fischer and Lenz<sup>2</sup> state that a simple dominant heredity is not the rule in diabetes mellitus. These observers hold that the reason for the difficulty in tracing the inheritance of diabetes mellitus through several generations is the inability or difficulty to recognize the disease, and also that many persons with potential diabetes die from other causes before true diabetes mellitus becomes manifest. It is the opinion of Baur, Fischer and Lenz that in most cases diabetes mellitus is the result of a recessive hereditary factor. Furthermore, the disease may skip one or more generations, and the genealogies in the literature generally support this view. Joslin<sup>3</sup> found that the disease goes down through the males rather than the females. The reason given is that every other pregnancy in a diabetic woman

TABLE 1.—Classification of Group of 1,663 Diabetic Veterans

	Number	Per Cent
True diabetes mellitus	1,473	88.6
Potential	149	8.9
Unclassified	28	1.7
Renal glycosuria	13	0.8
Totals	1,663	100.0

results in a stillborn infant. Pincus and White<sup>4</sup> hold that the incidence of diabetes is higher in families of diabetic patients than in families of nondiabetic persons.

Priscilla White<sup>5</sup> is of the opinion that diabetes mellitus is transmitted as a simple mendelian recessive. Pincus and White<sup>6</sup> hold that diabetes mellitus, because of the fact that it is frequently not immediately identifiable and is manifested in different individuals at different ages, is not as easily proved to be an inherited disease, although they found ratios consistent with simple mendelian recessiveness.<sup>1</sup>

White, Joslin and Pincus<sup>7</sup> found that the difference between the occurrence of diabetes in a diabetic and a control population was that 2 per cent of the parents of the control population had diabetes mellitus whereas 8 per cent of the parents of the diabetic patients had the disease. Diabetes occurred ten times more frequently in brothers and sisters of diabetic patients than in the control group.

In this connection it is important to bear in mind the fact that other factors than heredity play a part in the inception of the disease. Some of these factors are abnormal endocrine activity, obesity and infections.

From the Medical and Hospital Service, Veterans' Administration.  
Dr. Elliott P. Joslin of Boston and Dr. Louis I. Dublin of New York offered valuable suggestions in this work. Cooperation was given by the medical officers of the various Veterans' Administration Facilities.  
A. Bamberg, assistant statistician, and O. M. Allen of the Research Subdivision, Medical and Hospital Service, assisted in the statistical work of this study.

1. Joslin, E. P.: The Treatment of Diabetes Mellitus, ed. 5, Philadelphia, Lea & Febiger, 1935.

In a previous study I<sup>8</sup> found that 10.6 per cent of a group of 300 diabetic veterans gave evidence of a hereditary or familial history of the disease. Of this group of 1,663 veterans 145, or 8.7 per cent, gave a hereditary, familial or combined hereditary and familial history of diabetes mellitus. Of this number seventy-two gave a hereditary history, fifty-four gave a familial history and nineteen gave a combined familial and hereditary history of the disease.

Of the seventy-two veterans with a hereditary history, sixty-four gave evidence of true diabetes mellitus and eight of potential diabetes mellitus. The largest groups, thirty-one and thirty-three, showed the presence of the disease in the father and mother respectively.

Of the fifty-four veterans with a familial history of the disease, fifty were patients with true diabetes mellitus, two had potential diabetes mellitus, one had unclassified diabetes mellitus, and one had renal glycosuria. The largest groups, eighteen and thirty-three, showed the presence of the disease in the sister and brother respectively.

Of the nineteen veterans with a combined hereditary and familial history, seventeen had true diabetes mellitus and two had potential diabetes mellitus. The largest groups, four, three and two, showed the presence of the disease in father and brother, mother and brother, and mother and sister respectively.

#### AGE AT ONSET

In a previous study I<sup>8</sup> found that 25.3 per cent of a group of diabetic veterans gave evidence of the onset of the disease within the age group 30-35, 19 per cent within the age group 35-40 and 18 per cent within the age group 25-30. Seventy and nine-tenths per cent of the group gave evidence of the diabetic condition prior to age 40, while 29.1 per cent showed the presence of the disease after that age. In this connection it is desired to point out that the largest number of these diabetic veterans were World War veterans whose average age at the time of diagnosis was 33.7 years.

Pincus, Joslin and White<sup>9</sup> state that a true picture of the susceptibility to diabetes at various ages is given by the ratio of the number of persons developing the disease to the number exposed to the disease in those ages. In their study of the rate of onset of diabetes by age groups, these observers found that the maximum susceptibility to the development of the diabetic disease occurred in the sixth decade. More detailed figures showed that age 51 among males was the age of maximum susceptibility. The onset rates further indicated that there is a declining susceptibility to diabetes in the later decades.

Joslin<sup>1</sup> states that, in the past, discussions and statistics on the incidence of diabetes were wrong, because they were based on the dead instead of on the living. This observer in a study of the age at onset of 4,639 diabetic patients, treated between 1898 and 1933 found that the maximum susceptibility to the development of the disease in males occurred in the sixth decade; 24.19 per cent of the males gave evidence of the onset of the disease in this decade. The susceptibility to the development of diabetes rose steadily to this maximum and thereafter declined.

According to Joslin the most significant aspect of the onset rates is the declining susceptibility to diabetes

in the later decades, thus indicating that the disease is not characteristic of old age and is therefore not a manifestation of senility. It is his opinion that the onset of diabetes depends on a complex of events of endocrine origin which attain fruition between the ages of 40 and 60 years.

In a study of the age at onset of diabetes, Joslin showed that the acme of the onset of the disease comes in the five year period 50 to 54 years, during which period 14.4 per cent of the males give evidence of the disease. The onset rate was 10.3 per cent in the 40 to 44 year period, 12.7 per cent in the 45 to 49 year

period and 10.7 per cent in the 55 to 59 year period. The median age at onset for all the males was 46.5 years.

In this connection it might be stated that there is a difference between the onset rate of diabetes mellitus and the mortality rate of the disease. The onset rates indicate that after the age of 60 is reached the chance of developing diabetes mellitus decreases, while the mortality rates indicate that the older one grows the greater are the chances of dying from diabetes.

According to Joslin, the statistics point to two cardinal ideas: that (1) emphasis should be placed on the prevention of the onset of diabetes in middle life and (2) the chief concern in the treatment of the disease should be with its late complications, because at present few diabetic patients die when young or of diabetes per se.

Table 3 gives a classification of 1,663 diabetic veterans according to the type of the disease as well as the age at the time of onset of the diabetic condition.

8. Matz, P. B.: A Study of Diabetes Mellitus Among Ex-Service Men, Mil. Surgeon 68: 591 (May) 1931.

9. Pincus, Gregory; Joslin, E. P. and White, Priscilla: The Age Incidence Relations in Diabetes Mellitus, Am. J. M. Sc. 188: 6-12 (July) 1934.

In this connection it is important to remember that the average age of the entire veterans group (approximately 4,409,247) was 44 years at the time of this study, and, furthermore, 93 per cent of this number, or approximately 4,193,373, were World War veterans of an average age of 43 years.

A study of the data in table 3 indicates that the largest number, 850, or 51 per cent of the group of 1,663 diabetic veterans, gave evidence of the onset of the disease within the age group 30 to 39. It is further noted that 80 per cent gave evidence of the disease before the age of 40 and 20 per cent after the age of 40. The average age of the group of 1,663 veterans at the time of the onset of the diabetic condition was 33.7 years.

The data in table 3 are not in accord with the data of Joslin; the latter found that the acme of the onset of the disease comes in the five year period 50 to 54 years. In the ex-service group the acme of the onset of the disease appeared to be within the age group 30 to 34. The reason for the difference appears to be that we are dealing with a select group of young males, whose average age is approximately 44 years.

TABLE 3.—Age at Time of Onset

Totals	1,663	100.0	1,473	100.0	149	100.0	23	100.0	13	100.0
Av. age	33.7		33.5		35.4		35.8		30.5	

These data indicate that true diabetes mellitus as well as the other diabetic conditions may develop in the younger age groups and at a greater rate than is commonly supposed. It is safe to state that diabetes mellitus is a disease of youth as well as middle age. Furthermore, if the diabetic condition continues to appear in the higher age groups and at a higher rate of onset we may expect to see a larger number of diabetic veterans in the years to come, thus increasing the problem of the treatment of diabetic ex-service men in the Veterans' Administration.

#### DURATION OF LIFE

The prognosis and the duration of life in diabetes mellitus depend on a number of factors: first, the type of the disease, whether it is mild or severe; second, whether or not insulin is being administered; third, on the general physical condition of the patient aside from the diabetes; fourth, on whether or not complications or coexisting diseases are present; and, lastly, on whether or not the diabetic patient cooperates fully with his physician and undergoes the regimen according to the requirements in his case.

Joslin<sup>1</sup> states that in the Naunyn era (before 1914) the average duration of life subsequent to the onset of diabetes was 4.8 years. In the Allen period (1914-1922) the average duration had increased to six years.

In the early Banting period (1922-1925) the average duration was 7.6 years. In the middle Banting period (1926-1929) it had increased to 8.4 years. In the later Banting period from Jan. 1, 1930, to the present, the average duration had increased to eleven years.

Of the 1,252 living diabetic veterans who are being treated with insulin, 1,243 have a diagnosis of true diabetes mellitus and nine unclassified diabetes mellitus. Of this group 318, or 25.4 per cent, have survived the disease from six months to five years; 394, or 31.5 per cent, from five to ten years; 279, or 22.3 per cent, from ten to fifteen years, and 261, or 20.8 per cent, from fifteen to over eighteen years. Accordingly 43.1 per cent of the group of diabetic patients treated with insulin have survived the disease ten years or longer.

The longest duration of the group of 1,243 cases of true diabetes mellitus was forty-two years, the shortest eight months, and the average duration to the date of this study 9.1 years.

Of the nine living patients with unclassified diabetes mellitus the longest duration was sixteen years, the shortest duration was 3.6 years, and the average duration to the date of this study was 12.8 years.

Four hundred and eleven of the living diabetic patients are not receiving insulin as a routine treatment, 230 have true diabetes mellitus, 149 potential diabetes mellitus, nineteen unclassified diabetes mellitus and thirteen renal glycosuria.

Of the 411 diabetic or renal glycosuric patients 188, or 45.7 per cent, have lived from less than six months to five years; 119, or 29 per cent, have lived from five to ten years; forty-four, or 10.7 per cent, have lived from ten to fifteen years, and sixty, or 14.6 per cent, have lived from fifteen to over seventeen years. It is thus seen that 25.3 per cent of the group of diabetic patients not treated with insulin have survived the disease ten years or longer.

Of the 230 patients with true diabetes mellitus who were not treated by insulin, the longest duration up to the date of this study has been twenty-eight years, the shortest eleven months, and the average duration 7.2 years.

In the group of 149 patients classified as having potential diabetes mellitus the longest duration has been 16.7 years, the shortest duration four months and the average duration 6.7 years.

Among the nineteen patients with a diagnosis of unclassified diabetes mellitus the longest duration has been fifteen years, the shortest duration 1.5 years and the average duration 7.4 years.

Of the thirteen with renal glycosuria the longest duration has been twenty-one years, the shortest duration 3.8 years and the average duration 12.5 years.

#### INSULIN

In the management of true and unclassified diabetes mellitus it is essential that the treatment be individualized. If possible the patient should first be treated by a diet and an effort should be made to have the urine sugar free and the blood sugar reduced to a normal percentage. If an endocrine abnormality or gallbladder disease is a factor in the causation of the diabetic condition, an effort should be made to overcome or remove the cause. If, after a serious effort is made to reduce the hyperglycemia and to remove the sugar from the urine by diet and other measures, the desired results are not attained, steps should be taken to ascertain the number of units of insulin required to overcome the

diabetic condition and the patient should be placed on a combined dietetic and insulin regimen.

Joslin<sup>1</sup> states that diabetes is never complete. This complicates the problem of the therapeutics with insulin, because one never knows how much insulin the active pancreatic remnant yields and therefore how much insulin must be supplied to the diabetic patient.

In a previous study I<sup>8</sup> found that 240, or 80 per cent, of a group of 300 diabetic patients had received insulin during the course of treatment. Table 4 indi-

TABLE 4.—Number of Patients Receiving Insulin; Also Number Treated Without Insulin

cates that of 1,473 cases of true diabetes mellitus 1,243, or 84.4 per cent, had been treated by insulin and 230, or 15.6 per cent, had not received insulin. Furthermore, of twenty-eight patients with unclassified diabetes mellitus nine, or 32.1 per cent, had been treated by insulin and nineteen, or 67.9 per cent, had not received insulin.

In considering the question of whether a diabetic patient should or should not receive insulin the physician is confronted with a number of problems. In the first place it is important to know whether the disease is mild or severe, whether a dietetic regimen alone will control the hyperglycemia and glycosuria, and lastly whether the case is one of true or unclassified diabetes; if the latter, an effort should be made to eliminate or overcome the particular condition that may be the cause of the reduced carbohydrate tolerance.

It is believed that good medical practice dictates that insulin should not be administered until after other means such as diet, the correction of abnormal endocrine disturbance and the reduction of weight are first resorted to. When these measures fail, the physician may administer insulin to compensate for the reduced pancreatic activity.

#### RESULT OF TREATMENT

The result of the treatment of diabetes depends on the type of diabetic disease and its severity; also on the professional ability and judgment of the physician and the intelligence and cooperation of the diabetic patient. The physician who treats diabetes mellitus should be familiar with the nature of the various types of diabetic conditions, with the complications of true diabetes mellitus and with their proper management.

Numerous dietetic and therapeutic regimens have been recommended for the treatment of the disease. The adherents and proponents of each regimen are able to show good results with the particular treatment used. Accordingly, it is difficult for an impartial observer to decide which of the several regimens is the best for the patient.

It would appear that the ideal form of treatment is one that individualizes the diabetic patient and in which an effort is made to diminish the existing physiologic burden by reducing the intake of the protein, fat and

carbohydrate foodstuffs until the urine becomes sugar free and the blood sugar is within normal range. If glycosuria and hyperglycemia cannot be eliminated by a modification of the diet, it becomes necessary to administer insulin for that purpose as well as to assist the patient with the assimilation and oxidation of the requisite amount of foodstuffs to yield sufficient energy and maintain body weight.

It is essential for the physician who treats diabetes mellitus to teach the patient all he should know about the disease and its management. In other words, the treatment of the diabetic patient should include instruction in the fundamental concepts of the disease and its management.

As the diabetic patient dies usually from complications of the disease, it should be the aim of the physician to prevent complications, and if perchance any should appear, the patient should receive immediate appropriate treatment. Another objective of the treatment is to increase the patient's tolerance for carbohydrates.

In a previous study<sup>8</sup> in which an effort was made to ascertain the result of the treatment of a small group of cases of true diabetes mellitus without insulin, it was found that of a total of forty-four cases eighteen, or 40 per cent, of the number gave evidence of satisfactory control of the diabetic condition; in nineteen, or 43 per cent, the diabetic condition was partially controlled; five, or 11 per cent, were uncontrolled, and two patients, or 5 per cent, died following treatment.

In the study it was also ascertained that of 237 cases of true diabetes mellitus treated by insulin forty, or 17 per cent of the group, gave evidence of satisfactory control of the diabetic condition; in 156, or 66 per cent, the diabetic condition was partially controlled; twenty-nine, or 12 per cent, were uncontrolled; and twelve patients, or 5 per cent, died following treatment.

Table 5 indicates that of 230 cases of true diabetes mellitus that were not treated by insulin 146, or 63.6 per cent, gave evidence of satisfactory control; fifty-nine, or 25.7 per cent, were partially controlled, and twenty-five, or 10.7 per cent, were uncontrolled. Of 149 cases of potential diabetes mellitus 123, or 82.6 per cent, were controlled, and twenty-six, or 17.4 per cent, were partially controlled, and twenty-six, or 17.4 per cent, were uncontrolled.

TABLE 5.—Result of Treatment of 411 Diabetic Cases Without Insulin, by Clinical Classification of the Diabetic Condition

	Total Cases	Controlled		Partially Controlled		Uncontrolled	
		Num-ber	Per Cent	Num-ber	Per Cent	Num-ber	Per Cent

Totals.....	411		72.3		21.6		6.1

cent, were partially controlled. Of nineteen cases of unclassified diabetes mellitus the diabetic condition was controlled in sixteen, or 84.2 per cent, and the condition was partially controlled in three, or 15.8 per cent. Of thirteen cases of renal glycosuria twelve, or 92.3 per cent, were controlled and one, or 7.7 per cent, was partially controlled. Taking the whole group of 411 cases not treated by insulin, 297, or 72.3 per cent, were controlled; eighty-nine, or 21.6 per cent, were partially controlled, and twenty-five, or 6.1 per cent, were uncontrolled.

Table 6 indicates that of the group of 1,243 cases of true diabetes mellitus treated by insulin the diabetic condition was controlled in 382, or 30.7 per cent, the condition was partially controlled in 582, or 46.8 per cent, and the condition was not controlled in 279, or 22.5 per cent.

Of the nine cases of unclassified diabetes mellitus six, or 66.7 per cent, were controlled; two, or 22.2 per cent, were partially controlled, and one, or 11.1 per cent, was uncontrolled.

A careful study of the data in tables 5 and 6 indicates that insulin was used to a larger extent in the treatment of true and unclassified diabetes mellitus than

TABLE 6.—*Result of Treatment of 1243 Diabetic Cases with Insulin by Clinical Classification of the Diabetic Condition*

Unclassified diabetes mellitus...	9	6	66.7	2	22.2	1	11.1

were dietetic and other regimens. It was also noted that a much larger percentage of the cases of true diabetes mellitus had the disease controlled by diet alone than by the use of insulin. The reason is that the cases treated by diet were of a milder type than those treated by insulin. This is further supported by the fact that larger percentages of insulin-treated cases showed partial control, and complete uncontrol of the diabetic condition. It means that the condition of the diabetic patients treated with insulin was at times such as not to respond favorably to this therapeutic agent. The data further indicate that unclassified diabetes mellitus treated by insulin showed better results than cases of true diabetes mellitus similarly treated.

#### COMPLICATIONS AND COEXISTING DISEASES

The complications and coexisting diseases most frequently found in diabetes mellitus are diabetic coma, the various infections, cardiovascular renal disease and pulmonary tuberculosis.

The complications, sequelae and intercurrent diseases are of more serious import to the diabetic patient than is diabetes itself. It is the presence of one or more of the complicating or intercurrent diseases that makes the prognosis of the diabetic condition less favorable and interferes with the satisfactory treatment of the disease. Death of the diabetic patient is usually due to one of the complications or intercurrent infections rather than to diabetes mellitus itself.

In a previous study I<sup>8</sup> found that among a group of 300 diabetic patients 79 per cent gave evidence of one or more complicating or coexisting diseases. The most frequent coexisting diseases in the group studied were obesity, coma, arteriosclerosis, tonsillitis, caries of teeth, hypertension and tuberculosis. Joslin<sup>1</sup> refers to a group of 1,206 diabetic patients and thirty-seven patients with nondiabetic glycosuria who were admitted to the George F. Baker Clinic in 1934, 257 of whom had no complicating disease and the others giving evidence of one or more complications.

Table 7 indicates that among 1,663 diabetic patients included in the present study 1,770 coexisting or complicating diseases were noted, an average of 1.1 disabilities per patient. Among twenty-eight cases of

unclassified diabetes mellitus of the group, forty-six coexisting conditions were noted, or an average of 1.6 disabilities per patient.

The most frequent coexisting conditions found among the group of diabetic patients were cardiac disease, arteriosclerosis, hypertension, chronic tonsillitis, arthritis, chronic bronchitis, psychoneurosis, obesity, active and inactive pulmonary tuberculosis, and diseases of the kidneys.

The most frequent coexisting conditions are those referable to the vascular system; 365, or 21.9 per cent of the group, gave evidence of this type of complication. Arteriosclerosis and hypertension were present to the extent of 7.1 per cent and 7 per cent respectively. Heart disease was a complicating factor to the extent of 15.6 per cent. Certain of the other coexisting diseases such as arthritis, bronchitis and tonsillitis were in no way related to diabetes mellitus.

Diseases of the endocrine glands were found to the extent of 3.2 per cent. The most frequent gland affected was the thyroid. In a number of instances there was a pluriglandular involvement.

Obesity was present to the extent of 4.4 per cent and was in some way related to the diabetic condition.

Psychoneurosis was noted in 129, or 7.8 per cent, of the cases. A careful study of these cases revealed the fact that in sixty-five instances the psychoneurosis followed the inception of diabetes mellitus. It may be assumed therefore that the diabetic disease was a direct or contributing cause of the psychoneurosis. In twenty instances the development of the psychoneurosis preceded the inception of the diabetic condition. Accord-

ingly, the condition may be said not to be in any way related to the diabetic disease, except that the latter condition may have prolonged or accentuated the psychoneurosis. In forty-four instances it was not possible to ascertain whether a relationship between the two diseases existed.

Pulmonary tuberculosis, active and inactive, was found in 4.4 per cent of the patients. It was not much of a problem in the management of the diabetic condition.

A study of the various coexisting conditions found in diabetic patients indicates that the problem of the physician in the treatment of the diabetic patient is two-fold: first, the treatment of the diabetic condition and, secondly, the treatment of the complications and coexisting conditions. The complicating and coexisting conditions frequently have an unfavorable effect on the diabetic disease and on the prognosis of the case. It is the common experience of physicians treating diabetes that, no matter how well the patient is handled and how scientifically the dietetic regimen and insulin dosage are planned, the complications and coexisting diseases have an adverse influence on the therapeutic regimen.

#### COMMENT

This study of more than 1,600 living diabetic veterans includes two groups. One group gave evidence of diabetes during the military service, and the other group gave evidence of the disease at various intervals after discharge from the military service up to the time of this study. The survival period extending from the date of onset of the disease to the date of this study varied from six months to as long as forty-two years. These diabetic patients were treated by various regimens. In recent years, however, the treatment of the disease in the Veterans' Administration has been more uniform, owing to the standardization of its management, so that the results from now on will reflect the uniform treatment used. It must be realized, however, that while the management of the diabetic condition is standardized, the physicians treat their patients according to the indications present. Accordingly, the Veterans' Administration physicians find it necessary to deviate to a certain extent from the prescribed regimen because of individual characteristics of the diabetic patients and on account of the presence of complications or intercurrent diseases.

It would appear, therefore, that the results of the treatment of the various types of diabetes mellitus are not comparable, because of the varied regimens used in the past, and because of the existing variation in the clinical characteristics of the different cases. Accordingly, it is not possible to determine the therapeutic regimen which was found to be most effective in the treatment of this group of cases.

In reflecting on the diabetic patients included in this study, the first consideration is the classification of the diabetic disease. The study shows that the incidence of potential diabetes mellitus is higher among the group of veterans than is the experience in civilian life. It is possible that, as time passes, certain of the cases of potential diabetes mellitus will give evidence of being true diabetes mellitus and will be so classified. The incidence of unclassified diabetes mellitus is low. The reason is that, as the veterans grow older and become subjected to some of the diseases commonly associated with unclassified diabetes mellitus, the incidence of this type of diabetic condition may show an increase. The incidence of renal glycosuria is greater than in civilian experience. It is possible that some of the cases now classified as renal glycosuria may eventually be found to be cases of potential or true diabetes mellitus. Accordingly, the principal reason for the differences in the classification of the diabetic veterans as compared with civilian experience is the age of the veterans.

In this connection it is important to remember that the average age of the entire veterans' group (approximately 4,409,247) was 44 years at the time of this study and, furthermore, 93 per cent of this number,

or approximately 4,193,373, were World War veterans of an average age of 43 years. More than half of the diabetic patients gave a history of the onset of the disease within the age groups 30-39 years. Eighty per cent gave evidence of the disease before the age of 40, and 20 per cent after that age. The average age of the whole group at the time of onset of the diabetic condition was 33.7 years.

These observations support the opinion of Joslin and others that diabetes mellitus is not a manifestation of old age. As a matter of fact the age of onset of the diabetic condition in this group of veterans begins to ascend with the age group 25-29, it reaches its acme in the age group 30-39, and then it begins to descend. Whether or not the future will show a change of the statistical pattern and an increase will take place in the incidence of the onset of the disease as the veterans become older, similar to civilian experience, remains to be seen. Joslin observed that in his experience the acme of the onset of the diabetic disease occurred in the age period 50-54 years, during which time 14.4 per cent of the males of his group gave evidence of the onset of the disease.

Accordingly, it would appear that if measures are to be taken to overcome the disease it would be advisable to begin in the earlier age groups rather than in the middle life period. The data in this study point to the fact that diabetes mellitus is a disease of youth as well as of middle life.

In the consideration of the survival period of this group of diabetic patients it must be emphasized that they have been under treatment for various periods and by varied regimens; some of the patients have been treated with insulin and others without it. Those who have been under treatment for a number of years have recently been on a standardized regimen. The insulin treated patients with true diabetes have survived the disease on an average 9.1 years and are now of an average age of 42 years, while the small group of insulin treated patients with unclassified diabetes mellitus have survived the disease on an average 12.8 years and are now of an average age of 40.7 years. The patients with true diabetes not treated by insulin have survived the disease on an average 7.2 years and have reached the average age of 44 years; the veterans with potential diabetes have survived the disease on an average 6.7 years and are now of an average age of 42.3 years; the veterans with unclassified diabetes have survived the disease on an average 7.4 years and are now of an average age of 44.8 years; finally, the veterans with renal glycosuria have survived the disease on an average 12.5 years and have reached the average age of 43.

The variation in the survival period of the living diabetic patients is dependent on the length of time they have had diabetic disease to the date of the study. As these cases are still under treatment, the figures are not final. It is believed that the survival period of the patients not receiving insulin will eventually exceed that of the patients on insulin. This is based on the fact that the diabetic condition of those patients not receiving insulin is milder and that a larger percentage of these cases are being controlled as the result of the dietetic regimen used. The figures representing the survival period of the various groups of diabetic veterans should therefore not be taken as indexes of the comparative potency of the various regimens used.

In studying the duration period of the living diabetic veterans one is impressed with the fact that the average duration of the disease is more than nine years. When

one realizes that patients with a fatal form of the disease formerly died after a duration of the disease of 4.8 years following intensive treatment, one must conclude that an enormous advance has been made in the management of diabetes mellitus.

Of a total of 1,473 patients with true diabetes mellitus, 84.4 per cent had been treated with insulin and 15.6 per cent by diet and other measures. It is difficult to make a comparative estimate of the relative efficacy of insulin as compared with diet in the treatment of true diabetes mellitus, since patients with the disease in a milder form were usually placed on a dietary regimen, while the patients with severe diabetes were placed on insulin.

Of the group of 1,243 cases of true diabetes mellitus treated by insulin, 30.7 per cent were controlled, 46.8 per cent were partially controlled and 22.5 per cent were uncontrolled. Of the group of 230 cases of true diabetes mellitus not treated by insulin, 63.6 per cent were controlled, 25.7 per cent were partially controlled and 10.7 per cent were uncontrolled. This confirms the previous statement that the cases on insulin are more severe than those on a dietetic regimen; therefore a comparative evaluation of the efficacy of the two regimens cannot be made from the data available in this study.

In the discussion of the coexisting diseases of diabetes mellitus it was found that certain of the disabilities were related to the diabetic condition either as sequelae or as complications; others were intercurrent and unrelated infections or diseases. The conditions that might be considered related to diabetes mellitus are cardiac disease, arteriosclerosis, hypertension, psychoneurosis and obesity. The conditions that were found to be coexisting without in any way being related to diabetes mellitus are active and inactive pulmonary tuberculosis, chronic tonsillitis, arthritis, chronic bronchitis and kidney disease.

In this connection it is well to point out that any coexisting condition, especially an infectious disease, presents a problem that must be given serious consideration in the treatment of the diabetic condition. Frequently the dose of insulin must be increased to compensate for its reduced therapeutic effect because of the coexisting infection. Then, too, mild diabetic conditions that ordinarily can be treated by a dietetic regimen require insulin in order that the hyperglycemia and glycosuria may be controlled.

In the management of diabetes mellitus it is essential that the patient be discouraged from seeking hospital care for his diabetic condition, except in the early stages of the disease, or soon after the condition is diagnosed, at which time it is necessary for him to receive hospital instruction in the salient phases of the disease, in its dietetic management, in the technic of the self administration of insulin, in the treatment of hypoglycemia, and in the prevention of gangrene. As the disease lasts a lifetime, the patient should be permitted to treat himself from the standpoint of dietetics and insulin therapy. The physician, of course, must carefully supervise the patient's efforts in this direction. The patient should, in addition, be encouraged to earn a livelihood. He should exercise and should seek useful entertainment to overcome introspection.

#### SUMMARY AND CONCLUSIONS

1. Of the group of 1,663 living diabetic veterans included in this study, it was found that the incidence of potential diabetes mellitus was greater than in the

experience of Joslin and other observers. The explanation is that the veterans are a younger group of men of an average age of 43 years. It is possible that a number of the cases now classified as potential diabetes mellitus may eventually be found to be true diabetes mellitus. The incidence of unclassified diabetes mellitus was 1.7 per cent as compared with the experience of Joslin, who found that they constituted 10 per cent of a group of 13,000 diabetic patients. It is possible that a more direct relationship between coexisting disabilities and the diabetic condition will be established later as the veterans grow older, increasing the incidence of unclassified diabetes mellitus. The incidence of renal glycosuria is greater in this group than has been the experience of Joslin. It is possible that certain of these cases will eventually be classified as potential or true diabetes mellitus.

2. One hundred and forty-five, or 8.7 per cent, of the group gave a hereditary, familial or combined hereditary and familial history of diabetes mellitus.

3. Of the group of 1,663 diabetic veterans 850, or 51 per cent, gave evidence of the onset of the disease within the age groups 30-39 years. Furthermore, 80 per cent gave evidence of the disease before the age of 40 and 20 per cent after that age. The average age of the group of 1,663 veterans at the time of the onset of the diabetic condition was 33.7 years. The acme of the onset of the disease in the group studied appeared to be within the age group 30-34 years.

4. Of 1,473 cases of true diabetes mellitus, 84 per cent were being treated with insulin. Of twenty-eight cases of unclassified diabetes mellitus, approximately 32 per cent were on insulin therapy.

5. Of 1,252 living diabetic patients treated with insulin, 25.4 per cent have survived the disease from six months to five years, 31.5 per cent from five to ten years, 22.3 per cent from ten to fifteen years, and 20.8 per cent from fifteen to over eighteen years. The average survival period of this group of insulin treated diabetic patients to the date of this study has been 9.1 years.

Among 411 living diabetic patients who are not receiving insulin, 230 have true diabetes mellitus, 149 potential diabetes mellitus, nineteen unclassified diabetes mellitus and thirteen renal glycosuria.

Forty-five and seven-tenths per cent of the number have survived the disease from less than six months to five years, 29 per cent from five to ten years, 10.7 per cent from ten to fifteen years, and 14.6 per cent from fifteen to seventeen years or over.

Among the 230 cases of true diabetes mellitus not treated by insulin the average survival period to the date of this study has been 7.2 years. Among nineteen patients with unclassified diabetes mellitus not treated by insulin, the average survival period to the date of this study has been 7.4 years.

As these are living diabetic veterans, the average survival period for the various groups referred to will be greater as time passes.

6. Of 411 veterans under treatment for true, potential and unclassified diabetes mellitus, and also for renal glycosuria, and not receiving insulin, 72.3 per cent were controlled, 21.6 per cent were partially controlled and 6.1 per cent were uncontrolled.

Of the group of 1,243 cases of true diabetes mellitus treated by insulin 30.7 per cent were controlled, 46.8 per cent were partially controlled and 22.5 per cent were uncontrolled. Of the nine cases of unclassified diabetes

mellitus treated by insulin 66.7 per cent were controlled, 22.2 per cent were partially controlled and 11.1 were uncontrolled.

It is a fact that the diabetic cases in which insulin was not administered were of a milder type than those treated by insulin, so that a much larger percentage of the former had the disease controlled. Furthermore, larger percentages of insulin-treated cases showed partial control, and uncontrol of the diabetic condition, than were found in the cases not treated by insulin.

7. Among the total number of 1,663 diabetic patients, 1,770 coexisting or complicating diseases were noted, an average of 1.6 disabilities per patient. The most frequent coexisting disabilities were cardiac disease, arteriosclerosis, hypertension, psychoneurosis, obesity, active and inactive pulmonary tuberculosis, chronic tonsillitis, colitis, chronic bronchitis and kidney disease. Certain of the disabilities are in some way related to the diabetic condition either as sequelae or as complications. The other disabilities are merely intercurrent diseases or infections in no way related to the diabetic condition but having a profound influence on the treatment of the patients, especially those requiring insulin therapy.

## DURATION OF SPERM CELL MIGRATION IN UTERINE SECRETIONS

PRELIMINARY REPORT: MAXIMUM EIGHTY HOURS

WILLIAM H. CARY, M.D.

NEW YORK

The purpose of this report is to present a few carefully checked observations as to the length of time sperm cells retain normal morphology and migratory power (not merely viability) in the reproductive tract of women, an important subject concerning which there is much vague speculation, many unsupported and widely varying opinions, and a paucity of convincing data.

Vignes and Boros,<sup>1</sup> as well as Belonoschkin,<sup>2</sup> state that the survival of spermatozoa is not very long and probably does not exceed forty-eight hours, owing to the higher temperature of the pelvis as compared to that of the scrotum. The former, however, quote observations made by Huhner<sup>3</sup> in which one case is included of sperm cells living as late as 102 hours after coitus. Macomber<sup>4</sup> reported finding living sperm cells in the cervical secretions four days after copulation in seven cases, and as late as seven days after contact in one instance. On the other hand, Moench<sup>5</sup> takes the position that body temperature kills sperm cells in twenty-four hours in most cases and states that observations of longer vitality become a moral rather than a scientific issue. Hartman and Ogmo admit the probability of somewhat longer survival of fecundating power. Macias de Torrès<sup>6</sup> and those who subscribe to the most conservative estimates of sperm cell viability are largely influenced by consideration of heat activa-

tion and cell exhaustion or by observation of sperm cell motility in the normal ejaculate or in artificial mediums. Although I have found that cervical temperatures range from 98.6 to 99.2 F., I can confidently assert that under favorable conditions large numbers of sperm cells continue in active migration in normal cervical mucus many hours beyond the time when all travel has ceased in a direct specimen collected from the same source and observed at room or body temperature. This suggests a chemical rather than a thermal explanation, which I am now planning to investigate. (At a lower temperature, 10 C., or 50 F., viability of sperm cells is said to be greatly prolonged, owing to retarded motility). In one case migration was noted in the cervical mucus at an interval six times as long as the duration of motility in the direct specimen. Stokes<sup>7</sup> calls attention to the fact that active sperm cells are found in the male ejaculate from two to three weeks after vasectomy and states that there is no reason to assume that the female generative organs are more hostile to sperm cells than the seminal vesicles.

Nürnbergers<sup>8</sup> two cases reported sixteen years ago in which living spermatozoa were found in excised tubes thirteen and fourteen days respectively after the last reported intercourse have been repeatedly quoted in subsequent literary comments. Actually, sufficient data have not been published to justify a consensus, and one hesitates to draw general conclusions from one or two cases when the apparent duration of viability is so at variance with the prevailing theory. Therefore the examiner should not be biased and his report should include such supplementary details as are required for scientific interpretation. The discovery of widely isolated sperm cells exhibiting motility without locomotion is not convincing evidence of sustained fertility.

Not only is the accumulation of reliable data in enough cases to justify general conclusions as to the survival of sperm effectiveness under normal conditions highly important to consolidate our knowledge of the sequence of events in fecundation, but it may explain otherwise irreconcilable errors in computing the date of delivery and could conceivably be relevant to certain medicolegal questions. Furthermore, this information is absolutely essential if the limitations of the safe period are to be postulated from the period of ovulation, a question now eliciting much scientific and popular interest. The practical application of this knowledge to the problems outlined must, however, ultimately depend on the determination as to whether the fecundating power of spermatozoa is lost prior to visible change in structure and cessation of migration.

Professor Hartman,<sup>9</sup> in an exhaustive study of ovulation in the higher primates, calculates the safe period on the assumption that the reproductive vigor of sperm cells rarely persists beyond the thirty-sixth hour. He and other animal experimentalists point out that in certain lower animals in which copulation can be controlled with regard to known time of ovulation the evidence indicates that sperm motility continues longer than the power of fecundation. Vignes and Boros quote the experiment of Datwyler, which shows that whereas bull spermatozoa live forty-two hours in

Ringer's solution they survive only twelve hours in the uterine secretion. There is scant evidence that the secretion of the fundus uteri in human beings is more inimical to sperm cell survival than that of the cervix. If spermatozoa can lose their fecundating power by senility without alteration in morphology or serious impairment of motility, criteria are not available for accurate evaluation at the present time and the appraisal of the semen assumes greater difficulty.

#### CONDITIONS FAVORABLE TO INVESTIGATION

In the human species, reliable evidence on this subject is difficult to acquire. Conditions essential for investigation of maximum sperm survival include the good health of both sexual partners, a male specimen of normal characteristics and vigor, and cervical secretion in the female which provides a favorable medium for migration. Furthermore, there is evidence that in some women conditions most favorable to sustained motility are provided for only a limited part of the menstrual cycle. Several years ago I stated that in general the most satisfactory time for postcoital study was a few days subsequent to cessation of menstruation, owing to the increased secretion of less viscid mucus at that time, a condition often absent in patients with uterine hypoplasia. The reason was not then appreciated, but Papanicolaou, Hartman and other physiologists who subscribe to midmenstrual ovulation now consider increased secretion as a phenomenon of the high follicle period.

Because of the frequency of intercourse, the prevalence of contraceptive measures and the fact that the convenience of three persons is involved, it is difficult to arrange for proper timing of the examination. In my opinion deliberate arrangement solely for experimental purposes not only invites unadmitted errors due to conflict with the sexual habits of the couple but may introduce unpredictable factors which may vitiate the accuracy of results. Honest deductions cannot be drawn without confidence in the sexual history of the patient. It is obvious that such a happy combination of biologic conditions and concatenation of circumstances is not frequently presented by a woman who is forced to consult the gynecologist.

Granting that widely varying results may be reported in individual cases because of the many factors which affect the duration of sperm cell motility, it should be possible ultimately by accumulating reliable data to substitute fact for opinion as to average and maximum survival under normal conditions of fertility.

#### REPORT OF STUDIES

In 1929 I<sup>10</sup> reported an analysis of 250 postcoital studies made one hour after coitus and described the aspirating apparatus and technic modified after that of Huhner. At that time I was inclined to agree with Huhner that active sperm cells in the cervical mucus indicated the fertility of the husband. I have for some time questioned the accuracy of this conclusion, for motile sperm cells have been found in cases in which the direct male specimen was appraised as deficient according to the present criteria of evaluation. With the onset of the depression the technic was altered to enable out-of-town patients to make preparation at home, and it was noted that satisfactory studies could be made as late as six hours after coitus and, in occasional instances in which the husband was rendered

impotent by prescribed preparation, observations were successfully carried out from twelve to sixteen hours after intercourse. Thus, by evolution, my interest was recently stimulated in the later investigations.

The observations here presented were made incidental to other studies conducted under the favorable conditions previously outlined and in patients unaware of the nature of the examination, thus obviating any motive for deception. The cases reported are restricted to those in which an average of two or more well formed, actively migrating sperm cells per high power field were found in the deep cervical mucus and the patients, when interrogated subsequent to the examination, were able to fix the time of the last coitus at thirty-six hours or more before their visit. This arbitrary period was chosen because the observations of others and my own postcoital studies indicated that sperm survival in the female at periods of less than twenty-four hours was a frequent occurrence.

The term "normally migrating cells" refers to that characteristically undulating motion by which spermatozoa travel through a mucous medium in a more or less well sustained direction as opposed to the lashing tail with constantly changing direction noted in the seminal fluid, or the vibratory motion with sluggishly intermittent travel, or no change in position, noted in cervical secretion when the cell is exhausted or seriously obstructed by viscosity.

Four cases are abstracted in which migrating sperm cells were found from thirty-six to eighty hours after coitus. The report is necessarily preliminary in character as there is no reason to believe, under the conditions of examination, that the observations are exceptional or approach the potentialities of sperm survival.

CASE 1.—Mrs. E. M., aged 34, married two years, seen because of primary sterility, had uterine hypoplasia to a minor degree, and endometrial hyperplasia with stromal edema. Libido was reduced. There was mild hypothyroidism, but no other physical stigmas of endocrine disorder were present. The tubes were patent and menstruation was normal. The cervical mucus was highly variable as to viscosity without apparent reference to the menstrual cycle and therefore was frequently aspirated for study. Spermigration had previously varied from early failure to continuation at the twelfth hour. Feb. 28, 1933 (the fifteenth day of the cycle), normally migrating sperm cells were incidentally noted and the patient was able to fix the time of last coitus on the night of February 25, sixty hours previous to examination. Lacking precedent, the incredulity of the examiner persisted in spite of a positive patient, and the finding was simply recorded without the number of cells per field being noted. The husband was in vigorous health and a contemporary direct specimen showed a high cell count, with 88 per cent normal forms and well sustained motility not completely suspended at the twenty-fourth hour.

CASE 2.—Mrs. S. V., aged 28, was successfully treated for primary sterility associated with marked malnutrition, passive pelvic congestion, retroversion and cervical erosion, with secretion increased in amount and viscosity. Leukorrhea had persisted since early college years. One year subsequent to delivery this frail but determined patient complained of secondary sterility and insisted on more active management than the constitutional measures recommended. An appointment was made subsequent to the approaching period for restudy of spermigration. The patient came on the seventh day of the menstrual cycle without preparation and requested a tube test. Considerable clear mucus, occupying a gaping succulent cervix, was removed preliminary to insufflation and on microscopic examination from four to twelve vigorously migrating sperm cells were found per high power field. The canal was cleansed and another aspirating cannula easily passed to the cavity of the uterus, where a small amount of blood-stained mucus was

10. Cary, W. H.: Sterility Diagnosis: The Study of Sperm Cell Migration in the Female Secretions and Interpretation of Findings, New York State J. Med. 30: 131 (Feb. 1) 1930.

obtained, with similar results. The possibility of cervical contamination is admitted. Intercourse had occurred thirty-six hours before examination and the specimens were hardly distinguishable from normal one-hour postcoital examinations. Conception apparently occurred on the eleventh day of the second menstrual cycle thereafter. This experience altered my interpretation of the earlier case and stimulated subsequent interest in this subject.

CASE 3—Mrs H T, aged 27, with primary sterility, but no gross pelvic pathologic condition, was examined June 27, 1935, on the ninth day of the menstrual cycle. Clear, glistening mucus was aspirated from the cervical canal incidental to other study and when examined microscopically showed from two to four well formed, normally migrating sperm cells in each field. On inquiry the patient stated that the last intercourse occurred on Sunday night, June 23, approximately eighty hours previously. Confirmation of the date was received from the husband by telephone. A contemporary study of the husband's specimen revealed the total amount subnormal (from 2 to 25 cc), viscosity was variable, apparently because of undissolved mucus, the cell count was 73,000,000 per cubic centimeter, about 40 per cent of the cells were motile, with only a fair degree of traveling vigor, abnormal forms amounted to 13 per cent. The duration of motility was subnormal, showing marked reduction in five hours from four to five cells sluggishly crossing the field at the eighth hour and almost complete subsidence at the twelfth hour. This result was confirmed by subsequent examination. Under treatment this specimen improved as to total amount and sperm count, and initial motility was considerably increased but cessation in a direct specimen again occurred at approximately the twelfth hour. Nevertheless two contemporary examinations of the cervical mucus made thirty-six and sixty hours after coitus (the eighth and ninth days of the cycle) revealed in the first instance as many as sixteen spermatozoa per field with 33 per cent active travelers, on the following day, in spite of previous manipulation, most fields contained from one to four migrating cells. This indicates that, although motility may be an inherent quality of the cell, duration is controlled by the medium.

CASE 4—Mrs X, aged 35, seen Wednesday, Nov 20, 1935, a few days after the period, complained of one child sterility. This very tall, slender woman had not been well for some time, reporting a loss of 50 pounds (23 Kg) in eighteen months. Pregnancy was desired in the hope that she might regain the excellent health enjoyed during gestation six years previously. The uterus was retroverted, evidently complicating enteroptosis. A normal cervix contained clear mucus in abundance, and this was removed for viscosity study. Microscopic examination revealed from two to four normally migrating spermatozoa in each field, and while this was demonstrated to a confrere the nurse was sent to inquire as to the time of last coitus. Because of sexual routine the patient was able to state positively that coitus occurred at approximately 6 p m on the preceding Sunday, sixty four hours before her visit. As the patient was found to be suffering from hyperthyroidism the sterility study was discontinued and the husband's specimen was not examined.

Another finding of some interest but one that does not conform to specified requirements was made in a woman, aged 39, with uterine hypoplasia and scant cervical mucus slightly increased in viscosity, in which from one to three viable (motile but nontraveling) spermatozoa were found in occasional microscopic fields eighty-four hours after coitus. The husband's specimen exhibited unusual vigor. Dead or inactive sperm cells were not found in large numbers in any of these latest investigations, possibly owing to drainage in a mucous stream which vigorous cells ascend.

I have found most patients rather vague or uncertain as to the time of last coitus after a period of more than four days has elapsed. In three cases presenting favorable conditions "a week or so" after coitus, no sperm cells were found. Negative examinations are of little significance unless all factors conducive to sperm sur-

vival are known to exist. Some form of contraception is practiced by most patients unless they are consulting the physician for sterility, and in this group conditions unfavorable for this study are frequently met.

It should be stated that this contribution is offered in the hope of stimulating the publication of further data relevant to this important question.

## OBSERVATIONS ON THE VARIATIONS IN BILE PRESSURE IN THE HUMAN BILIARY TRACT

HAROLD A KIPP, MD

PITTSBURGH

My purpose in this paper is to present some changes noted in the pressure of bile in the human biliary tract. The fact that these observations were made in the course of an examination of a patient for another purpose, and that subsequent review of the literature gives no similar record of bile pressure in the human being, leads me to think that perhaps these are original observations.

The patient who recorded these pressures was a man, aged 78, who had been jaundiced for more than two years. I operated on him, Jan 26, 1934, with a local anesthetic and found a benign stricture of the common bile duct at the ampulla of Vater. The gallbladder was greatly distended with 650 cc of clear light brown bile. The liver was greatly enlarged and intensely bile stained. The common bile duct was opened, explored with the finger and a probe 0.5 cm in diameter forced through the ampulla into the duodenum. I then performed a cholecystogastrostomy and placed a T tube in the common duct.

The patient had a stormy convalescence, during which time his immediate direct Van den Bergh reaction, with 185 mg of bilirubin per hundred cubic centimeters of blood serum, observed before operation, fell to normal. Bile was drained continuously through the T tube for several weeks and on March 9 he was discharged from the Mercy Hospital with the tube in place, closed with a small screw clamp and later a wooden plug. Bile pigment had meanwhile appeared in the stools and the icterus, with its accompanying pruritus, for relief of which he had sought operation, had disappeared.

Because of his age and general condition and the fear of the often reported ascending infection of the biliary tract in postoperative cholecystogastrostomy cases, I hesitated to remove the T tube from the common duct. From it at intervals, however, clear yellow bile was withdrawn, which showed at times a slight mucous sediment. No sign of infection made its appearance. However, there was always the question from the patient of how long he would have the tube.

I had the idea that, if the pressure of bile in the T tube was high its removal would be followed by a chronic bile fistula and early death. As generally known, either following cholecystostomy, in the presence of obstruction of the cystic duct, or choledochostomy, in obstruction of the common duct, if the obstruction has been removed and a clear flow of bile is obtained, the bile fistula closes promptly. This case

was complicated by the presence of an unrelieved obstruction at the region of the ampulla, as demonstrated by the injection of 15 per cent sodium iodide solution through the T tube (fig. 1) and the cholecystogastrostomy.

The patient was doing very well, so the T tube was left in the common duct. The bile was draining very well through the cholecystogastrostomy and in case this

distance traveled in the excursion of the fluid level in the manometer, certainly within the error of our crude method, this figure was considered bile pressure. The corresponding average pressure on the manometer on expiration, which would more nearly represent the normal tension of the bile in this system, uninfluenced by the extrinsic factor of respiratory effort, was  $5\frac{1}{10}$  inches, or 142.5 mm. of bile. This figure may then be taken as the approximately normal pressure of the bile in the common duct in this patient, in whom the biliary tract is not intact because of the closed sphincter of Oddi and the substituted outlet of cholecystogastrostomy, with a T tube in the common bile duct, leading to the exterior of the body.

The difference in pressure of 17 mm. of bile therefore represents in this instance the increase in pressure in this biliary tract, i. e., the common duct, produced by a normal inspiration. The variations in pressure in the biliary tract during the course of these observations, as noted in table 1 and figure 3, are small and the pressures tend to stay at a fairly constant level.

The exceptional variations in tension under the influence of other extrinsic factors were noted as follows: When the patient took a deep breath the pressure was raised both on inspiration and on expiration; on deep inspiration, 8 inches; on expiration after a deep inspiration,  $6\frac{1}{2}$  inches. When the patient coughed, the pressure rose to 14 inches, or 350 mm., and the pressure returned quickly to normal, so that in ten minutes it was at its previous tension. Another cough raised the pressure to 16 inches, or 400 mm. After this hard cough there was an appreciable lowering of tension in the bile tract, as noted. The pressure then on inspiration measured  $5\frac{1}{2}$  inches and on expiration  $4\frac{3}{4}$  inches.

anastomosis opening became obstructed, I considered the well organized fibrous tract around the T tube a potential anastomotic duct, which could be implanted into the bowel.

In a further effort to determine the risk of removing the T tube, I thought that if the pressure in the tube was not high and since the patient was ambulant, if it was no higher when he stood erect than when he lay down it might safely be removed.

Sept. 7, 1934, I arranged a manometer with a 4 mm. inside diameter and a scale in inches (fig. 2) for the measurement of bile pressures. This was connected with the T tube in the common bile duct. The diameter of the manometer and the connections and the T tube was approximately the same. The connections of the system were filled with physiologic solution of sodium chloride to exclude air, and the bottom of the manometer was fixed at a level as nearly approximate as possible to that of the common bile duct, with the patient lying on his back.

The following observations were recorded on the fluctuations of the level of the pressure in the common bile duct as registered on the manometer:

Analysis of record of pressure variations is given in table 1 and figure 3. The variations in pressure as noted on normal inspiration and expiration were recorded every ten minutes. The average of the pressure readings on inspiration and expiration, with the exception of the wide fluctuations noted, so as to arrive at an average pressure of bile in the normal, quiet resting patient, lying on his back, in each of these respiratory phases was calculated. For normal inspiration, this amounted to  $6\frac{3}{100}$  inches, or 159.5 mm. of bile. Since the specific gravity of physiologic solution of sodium chloride and bile in the common duct is approximately the same, and discounting the difference in viscosity of the two solutions because of the short

The numbers in parentheses refer to corresponding numbers in figure 4.

This effect was small but may indicate that the extreme elevation of the pressure on coughing may have caused a discharge of bile from the tract through its exit into the stomach sufficient to account for the lowering of the pressure. Another cough raised the pressure to 20 inches, or 500 mm.

Laughing raised the pressure to  $15\frac{1}{2}$  inches, or 387.5 mm. The patient was fed a fat meal and there

was apparently a slight rise in pressure. This rise may have been occasioned by increased peristalsis in the stomach or some other factors. This rise was followed by a fall in pressure. Considering the method and the percentage of error possible, this variation was not considered significant.

At this time I had the patient stand and the pressure rose to  $13\frac{1}{2}$  inches on inspiration and  $12\frac{1}{2}$  inches on

Fig. 1.—Sodium iodide injection of biliary tract.

expiration. This elevation of pressure in the duct, in the erect position, led me to postpone the removal of the T tube.

The patient continued for a year with the tube, experiencing slight inconvenience. No leakage of bile occurred around the tube. However, he was sufficiently annoyed to want the tube removed.

Oct. 26, 1935, another series of pressures was estimated by the same method. In this series of observations, as seen in table 2 and its accompanying graph (fig. 4), the pressure on normal and deep inspiration and the pressure after a normal and after a deep inspiration were recorded as well as the variations in pressure produced by other factors.

It was found that the average pressure on normal inspiration was  $6\frac{5}{100}$  inches, or 163.25 mm. of bile. This figure is approximately the same average pressure as in the preceding series of similar observations and serves as a fairly good check on the method, the former comparable reading being 159.5 mm. of bile. The average pressure on deep inspiration was  $8\frac{5}{100}$  inches, or 220 mm., of bile. The average pressure in this series after normal inspiration, i. e., normal expiration, was  $5\frac{1}{2}$  inches, or 137.5 mm., and after deep inspiration was  $5\frac{5}{100}$  inches, or 139.5 mm., of bile. These pressures were very nearly the same and compare closely to the observations under similar circumstances in the

series a year previously, which were  $5\frac{7}{10}$  inches, or 142.3 mm., of bile. The figures for expiration in the two series of observations are approximately the same and an average of the three average figures, or 139.8 mm. of bile, may be taken as the normal tension of the bile in the common duct in the patient's biliary tract.

Significant changes in pressure were also recorded on moving the patient's right leg, talking, coughing and restless moving about of the patient on the table, as seen in table 2 and figure 4. When the patient sat up on the table, moving the manometer to correspond to the change in position of the common duct, the bile pressure was increased to  $13\frac{1}{2}$  inches, or 337.5 mm., on normal inspiration, and 17 inches, or 425 mm., on deep inspiration, with a return to  $11\frac{1}{2}$  inches, or 287.5 mm., on expiration. These pressures were higher than those produced by the patient's standing. This is probably due to the fact that in the sitting position there was considerably more compression of the contents of the abdomen.

These elevations of pressure within the biliary tract of the patient, as recorded, caused me to be very hesitant to disrupt a working scheme in an elderly patient, subject to the possible accidents to his altered biliary tract. He was allowed to keep his T tube until Jan. 13, 1936, when, because of its being a possible cause of some epigastric discomfort, it was removed without difficulty and found to be open in good condition. Bile drained profusely from the opening until January 18, five days later, when it stopped. The wound has been healed since, without further drainage of bile. Bile appears regularly in the stool and there is no icterus.

The results obtained in these two series of observations on the variations in pressure in the human biliary tract, altered as it may be in this patient, are interesting when compared with the various observations made on the biliary tract pressures in dogs, particularly experimental work done on animals to determine the various forces which combine to cause a flow of bile from the liver cells into the duodenum. In this case the factor of sphincter control of the bile

Fig. 2.—Design of apparatus for measuring bile pressure: Sc, scale; M, manometer; T, tube; CD, common duct; St, stomach; D, duodenum; GB, gallbladder.

entering the duodenum may be disregarded, as shown by the injection of the radiopaque sodium iodide solution. The duration of the patient's jaundice for a period of two years, however, would suggest that the obstruction at the ampulla of Vater was not complete. The fact that there was found at operation fairly

normal-appearing pigmented bile, rather than white bile,<sup>1</sup> in the greatly enlarged gallbladder, the walls of which were not disabled beyond the point of some degree of compensatory resorption, would suggest this conclusion. Judging, however, from these factors and the extensive bile staining and enlargement of the liver, the pressure necessary for bile to flow into the duodenum through this narrowed opening must have been very high. That the obstruction was becoming greater

Fig. 3.—Bile pressures, Sept. 7, 1934 A, expiration, B, inspiration

is proved by the intensification of the patient's icterus and the rise in the bilirubin in the blood from 12.5 to 18.5 mg. in the two months preceding operation. The fact that no radiopaque solution flowed into the duodenum at the time of the visualization of the bile tract is suggestive that the ampulla was closed but further not conclusive, since the observations under the fluoroscope and the subsequent taking of films were continued for too short a time to tell whether or not some of the fluid might have entered the duodenum. However, since the hepatic ducts and the gallbladder were filled with the contrast medium, without the appearance of the iodide solution in the duodenum the ampulla of Vater must be rather firmly closed. The duodenum was not opened at the operation and the ampulla was not directly observed. Sufficient damage had been done the patient. The difficulty with which a probe was passed through the ampulla into the duodenum and the absence of any palpable stone or tumor, together with the fact that the patient still lives without icterus or palpable evidence of abdominal tumor, might be considered sufficient evidence of the presence of a benign stricture. Thus it may be assumed that in this case the ampulla of Vater is closed and thereby eliminated as a factor in the control of pressure variations in this biliary tract.

Experimental evidence of the rôle of the gallbladder in controlling bile pressure may then be considered. Introduction of a metal cannula into the fundus of the gallbladder in the experimental animal has appar-

ently not interfered with its contractile power. Potter and Mann<sup>2</sup> found a rise in pressure of 68 mm. of water in the gallbladder of the dog after a milk feeding, as compared to a rise of 35 mm. in the common duct. Therefore tonus, elastic recoil, as shown by Copher, Kodama and Graham,<sup>3</sup> and contractile power of the gallbladder, as demonstrated by Ivy,<sup>4</sup> may be considered in the presence of a cholecystogastrostomy.

The secretory pressure of bile, as measured in the dog by Winkelstein and Aschner,<sup>5</sup> amounted to from 60 to 70 mm. of bile. This, then, is an additional factor to be considered in maintaining the pressure recorded in the common duct.

Elman and McMaster<sup>6</sup> observed in a normal, unanesthetized dog that from 100 to 120 mm. of bile pressure produced a flow of bile in the duodenum from four to twelve hours after feeding, but that in a fasting dog between 200 and 300 mm. of bile pressure was necessary to cause a flow of bile into the duodenum. Potter and Mann<sup>2</sup> observed that the average biliary pressure in the quiet, intact, unanesthetized dog was 120 mm. of water, which they considered bile pressure. These men also record the resistance of the sphincter of Oddi to passage of bile into the duodenum as observed by others to vary from 60 to 625 mm., the average pressure, excepting the highest one, recorded by Oddi himself (625 mm.), being 158.5 mm. Therefore in dogs under experimental conditions a pressure of from 60 to 158.5 mm. of bile has been found necessary to produce a flow of bile through the sphincter of Oddi.

Regulation of flow of bile through the cystic duct has been studied; since it is a factor in this case, although the physiologic mechanism has been disturbed, the experimental observations are of interest. Winkelstein and Aschner<sup>5</sup> state that the cystic duct offers a resistance of 30 mm. of bile, while Rous and McMaster<sup>1</sup> found that a pressure of 60 mm. of bile was sufficient to fill the dog's gallbladder through the cystic duct.

In this pressure system the control of the opening between the gallbladder and the stomach remains to be

Fig. 4.—Bile pressures, Oct. 26, 1935. A, normal expiration, B, normal inspiration, C, deep inspiration.

considered. Its size is unknown and its variation in position and size under peristaltic movements and size of the stomach and posture of the individual is a matter of speculation. Bile has occasionally been regurgitated

from the patient's stomach. It has appeared regularly in the stool and there has been an absence of icterus.

It might be concluded, concerning the anastomotic opening, that the flow of bile into the stomach is regulated by the secretory pressure of the bile, the resistance of the cystic duct to its passage, the elasticity, tonus and contractile power of the gallbladder, the size of the opening, the peristalsis of the stomach and the extrinsic factors observed on the pressure records.

Since the mechanism provided at operation for this patient works and the bile pressures in man necessary to discharge bile into the duodenum or stomach are not recorded, the only figures with which to compare those recorded here are the figures for the experimental dog. Thus the average pressure in the human common duct, under these circumstances, in normal expiration is apparently 139.8 mm. of bile. With deep inspiration this pressure may rise to 220 mm. of bile, a rise in pressure of 80.2 mm. of bile. This increase in pressure in the human common bile duct, if the rise as recorded necessary in the dog is comparable, hardly suffices to force bile into the duodenum or stomach. However, on coughing, laughing, sitting up and standing, a rise of approximately 250 mm. to 260 mm. of bile in the human being would probably promote the flow of bile into the duodenum or stomach.

Might it not be too trite to suggest, in view of the rise in pressure in the biliary tract, in coughing, laughing and standing, that in our smoky Pittsburgh atmosphere our chronic coughs may have the virtue of alleviating to some degree the melancholy of our dark winter days by relieving us of some of our bile; that the old adage of "laughter with our meals makes for better digestion" has a physiologic basis, not only in the release of inhibitory impulses but also in increasing the flow of bile into the digestive tract? Finally, may we not consider our standing hot dog lunch counters a great advance from the time of the Romans, who ate reclining, to their detrimental disengagement?

The clinical value of these observations is problematic. Certainly with refinement in technic and a greater number of records in cases in which the biliary system is intact except for a tube in the gallbladder or common duct, with simultaneous observations of the movements of the duodenum and the appearance therein of bile, the normal response to food, chemicals and drugs and other extrinsic factors may be studied and a better understanding of the human mechanism of the flow of bile achieved.

#### CONCLUSIONS

1. Certain variations have been noted in the pressure of bile in the human common bile duct.
2. Extrinsic factors have been demonstrated which may influence the flow of bile.
3. The healing of biliary fistulas is accomplished by factors other than the lowering of pressure within the biliary tract.

**Diagnosis of Yellow Fever.**—I can remember when it was believed that an expert could make a diagnosis of yellow fever even in mild cases just from the clinical symptoms. After studying the disease in an endemic center from 1906 to 1910, I gave it up and said that I at least could not. Today we know that in endemic centers it frequently happens that the majority of cases occurring in the local population are unrecognized. Time and again in recent years by blood surveys and protection tests it has been found that yellow fever has occurred off and on for years in certain localities without its presence having been known.—Lloyd, B. J.: *Public Health Significance of Our Newer Knowledge of Yellow Fever, South. M. J.* 29:533 (May) 1936.

## PRESSURE IN THE COMMON BILE DUCT OF MAN

### ITS RELATION TO PAIN FOLLOWING CHOLECYSTECTOMY

JOHN M. McGOWAN, M.D.  
WINFIELD L. BUTSCH, M.D.  
Fellows in Surgery, the Mayo Foundation  
AND  
WALTMAN WALTERS, M.D.  
ROCHESTER, MINN.

The importance of the function of the sphincteric mechanism at the lower end of the common bile duct and the clinical application of knowledge concerning it in the management of disease of the biliary tract have of late been receiving a great deal of attention. Ivy and Sandblom<sup>1</sup> in this country, Schmieden and Niessen<sup>2</sup> in Germany and Pavel<sup>3</sup> in France have been in the fore in the elucidation of the types of biliary dyskinesia and of the symptoms which they produce. These men have applied knowledge gained from animal experimentation to clinical studies of cases and to operative results.

We have interested ourselves in direct measurement of changes in physiologic functions of the common bile ducts of human beings who have disease of the biliary tract. With the consent of the persons concerned, we have determined changes in pressure in the common bile duct of individuals into whose common bile duct a T-tube has been inserted previously, in the course of operation, for prolonged biliary drainage. Reports of direct measurement of pressure in the common bile duct of man have not been found in the literature. Cholechochography has proved to be a valuable adjunct to our studies.

The existence of a sphincter, the first description of which by Gage<sup>4</sup> was later amplified by Oddi,<sup>5</sup> or the exact anatomic nature of a sphincter, is not our concern. The functional capacity of the sphincteric mechanism at the lower end of the common bile duct, and not the question of exactly what muscle fibers are included in its structure, has engaged our attention.

#### REVIEW OF RELEVANT LITERATURE

Judd and Mann<sup>6</sup> in 1917 drew attention to the importance of the sphincter of the common bile duct in surgical conditions when they demonstrated the dilatation of the common bile ducts of dogs that follows removal of the gallbladder. They showed that this dilatation does not occur when the sphincter of the common bile duct is cut at the time of cholecystectomy. Changes of pressure in the common duct were measured by Potter and Mann<sup>7</sup> by inserting a T-tube into the common bile duct of the dog. They discovered that pressure in the duct increased markedly following cholecystectomy. They found that rhythmic

changes in pressure occurred and that the pressure could be influenced by the diet of dogs; that milk caused the highest pressure, that dog biscuits gave an intermediate reaction, and that fasting was accompanied by the lowest pressure. Giordano and Mann<sup>8</sup> showed that alkali placed in the duodenum increased, and that acid decreased, the resistance of the sphincter of the common bile duct of the dog. They also demonstrated

common bile duct by injecting into it bromipin, a substance that is opaque to roentgen rays. These studies were reported in detail at the meeting of the Interstate Postgraduate Medical Assembly in 1935. Following introduction of bromipin, if there was any persistent pancreatitis with narrowing of the bile duct, any reflux of bile into the duct of Wirsung or any disturbance of the sphincter of Oddi, roentgenograms gave evidence of the conditions.

It has been recognized that residual pancreatitis might lead to recurring attacks of abdominal pain, like that of biliary colic, but narrowing of the pancreatic portion of the common duct caused by swelling of the pancreas has not been emphasized as a mechanism by which the attacks are produced. Generally speaking, too little attention has been given to the effect of reflux of bile into the duct of Wirsung as a causative factor of pancreatic swelling. Similarly, abnormal function of the sphincter of Oddi, either from inflammation, spasmodic contraction or fibrotic stenosis, has not received the attention and study which it deserves as a factor in producing biliary stasis.

#### METHOD OF PRESENT STUDY

These studies were made in cases in which the gallbladder had been removed and a T-tube had been left in the common bile duct for drainage. The apparatus for measuring changes in pressure in the common bile duct consisted of a spinal fluid manometer fitted in the vertical position on a frame attached to a ring stand (fig. 1). The manometer was connected to the T-tube in the common duct by means of a rubber tube. This rubber tube was interrupted in the middle by a glass Y-tube, one limb of which was attached to the rubber tube on the manometer while the other was connected

Fig. 2.—Intraductal pressure following administration of one-sixth grain (0.01 Gm.) of morphine subcutaneously.

to the rubber tube that led to the T-tube in the common duct. The stem of the glass Y-tube was attached by means of a rubber tube to a bottle which acted as a reservoir for physiologic solution of sodium chloride. This type of bottle has been described previously by Osterberg and Little.<sup>12</sup> The rubber tubes were filled with saline solution from the bottle, and the rubber

12. Osterberg, A. E., and Little, G. G.: An Apparatus for the Preparation and Intravenous Administration of Various Fluids in Large Quantities, *Proc. Staff Meet., Mayo Clin.* 10: 241-245 (April 17) 1935.

tube leading from the reservoir was then clamped off. This left a continuous column of fluid from the common duct to the manometer.

To take the readings, the reservoir bottle was held in the hand at a low level. It was gradually elevated until the solution was flowing freely, which was indicated by air bubbling up into the bottle. The pressure at this point was that necessary to force the solution into the duodenum. This is referred to as the "perfusion" pressure. When the tube to the reservoir bottle was clamped off, the pressure as recorded in the manometer fell at a variable speed to a fixed level.

Fig. 4.—Cholangiograms. *a*, without morphine; *b*, seven minutes after administration of morphine.

which is referred to as the "intraductal" pressure. As the pressure in the common duct increased, the fluid in the manometer rose. For the purpose of making permanent records, a U-shaped tube in the form of a water manometer, with a float and writing styllet on one side, was substituted for the spinal fluid manometer; changes in pressure were recorded on a smoked drum.

The method used for making roentgenograms of the common duct was as follows: A sterile 10 cc. Luer syringe was fitted into the end of the T-tube and the bile was aspirated. Five cubic centimeters of lipiodine was injected and a roentgenogram was made. The opaque substance usually went in without much pressure. The process was repeated for verification five minutes later. Morphine, one-sixth grain (0.01 Gm.), was then given subcutaneously and the pressure manometer was connected to the T-tube. When the full morphine effect was present, as was indicated by the reading of pressure, the manometer was disconnected. Bile flowed freely from the T-tube for a time. The content of the T-tube was then aspirated in order to remove as much bile as possible from the biliary system.

The opaque substance was then injected slowly. From 3 to 5 cc. went in easily, at which point a sensation of pressure was transmitted to the hand from the syringe. Injection was then stopped and a roentgenogram was made.

#### RESULTS

Studies of pressure were made on fifteen occasions; the subjects were eight different patients and all of them were at rest while the studies were in progress. The pressure, measured by a column of fluid above the level of the abdominal wall, ordinarily is between 0 and 30 mm. of water. Respiratory excursions cause the pressure to rise from 5 to 10 mm. of water. A more detailed report of the intraductal pressure in different conditions will be given later.

It was found that morphine sulfate, one-sixth grain (0.01 Gm.), given subcutaneously, produced an increase in intraductal pressure on fourteen occasions (fig. 2). Pressure began to rise from two and a half to four

minutes after administration of morphine. It rose rapidly and reached a plateau from ten to fifteen minutes after the injection.

Rise in pressure was associated with constant pain in one case. This pain was situated in the right upper abdominal quadrant and extended around the right subcostal margin. Pain also was present at the same time in the right scapular region and extended up toward the right shoulder. This was the same type of pain from which this patient had suffered since removal of her gallbladder a year previously. She would wake after midnight, frequently in pain. Attacks were often severe, lasted as long as an hour, and were accompanied by nausea. In addition, she complained of frequent cramps in the right upper abdominal quadrant, which came and went during the day.

The manometer was connected to the T-tube on two separate days and was left in place for several hours in order to get a reading in the course of an attack of pain. In all, five attacks of pain occurred in the course of the study, and accompanying each was a rise in pressure (fig. 3). The duration and severity of the pain corresponded in each case with the size of the pressure curve. On one occasion the pressure was as high as 160 mm. of water. The manometer was so situated that the patient was unable to see it, ruling out, as far as possible, any psychologic element.

The pain that followed administration of morphine began shortly after the pressure started to rise. It became increasingly severe in the next ten minutes and then gradually became less severe, no doubt because of the analgesic action of morphine on the higher nerve centers.

Pain persists throughout the whole time of the rise in pressure, which is about two hours. Because of inconvenience to patients, the pressure curve was not followed to its conclusion on more than two occasions. The pressure rises, under the influence of morphine, from 0 to 200 or 350 mm. of water. The perfusion pressure is also elevated, usually from 140 mm. to 400 or 600 mm. of water. The point and mode of action of

Fig. 5.—Cholangiograms: *a*, without morphine; intraductal pressure at 20 mm water, and *b*, thirty-one minutes after administration of one-sixth grain (0.01 Gm.) of morphine subcutaneously; intraductal pressure at 120 mm water.

morphine on the biliary system offers a large field for speculation. This much evidence is available: 1. Fluid can be made to flow from the common bile duct into the duodenum after administration of morphine only by increasing the pressure. In other words, the perfusion pressure is increased. 2. Roentgenograms made before administration of morphine give evidence of rapid emptying of the common duct; the opaque medium usually is found in the duodenum. Roentgenograms of the same patients after administration of morphine give evidence of distention of the common duct.

Opaque substances remain in the hepatic ducts and smaller branches of the biliary tree and the lower end of the common duct tapers to a sharp point, suggesting muscular spasm; the picture is not unlike that of the esophagus in the presence of cardiospasm (figs. 4 *a* and 4 *b* and figs. 5 *a* and 5 *b*).

Since muscle spasm suggested itself as the main factor in the phenomenon described, drugs that might cause relaxation were tried to counteract the spasm caused by morphine and subsequently to relieve the patient's pain. A therapeutic dose of the relaxing drug was given in order to be sure that it did not produce a rise in pressure. Then morphine, one-sixth grain

Fig. 6.—Effect of amyl nitrite at the height of pain that followed administration of morphine. Inhalation of amyl nitrite brought a complete drop in pressure and relief of pain. As the effect of amyl nitrite wore off, morphine again produced an increase in pressure, which was again relieved by inhalation of amyl nitrite. (Each stroke of the timer represents five seconds; each group of strokes represents one minute.) At 2, morphine was given; at 5 the patient complained of cramping pain; at 6, pain was severe; at 8, pain had disappeared; at 9 and again at 10 it had returned.

(0.01 Gm.), was given subcutaneously. When the pressure reached the peak, a second dose of the relaxing drug was given to see if it would lessen the pressure caused by morphine. No depressor effect was produced on the morphine curve by atropine, histamine, phenobarbital sodium, alcohol or acetylsalicylic acid. A definite transitory decrease was noticed after small doses of epinephrine, but it made the patient uncomfortable.

The drug that produced complete disappearance of pressure and absolute relief of pain was amyl nitrite. A few whiffs of this drug almost at once brought the pressure down to zero, where it remained for a few minutes and slowly returned, after about fifteen minutes, to the level at which it had been after administration of the morphine. At the same time that the pressure fell, the patient was completely relieved of pain (fig. 6).

Glyceryl trinitrate produced a partial effect. It was about a third as effective as amyl nitrite in depressing the curve that followed administration of morphine. However, it seemed of sufficient effect to cause relaxation of the spasm which produces the pain from which the patient ordinarily suffers. At present the patient mentioned in a preceding paragraph is being given one one-hundredth grain (0.0006 Gm.) of glyceryl trinitrate when she has an attack of pain. She claims relief in from five to ten minutes. However, the symptoms are subjective and it is very difficult to measure the amount of relief. After a year it has been found that although the various analgesics, very frequently morphine, do not relieve pain, glyceryl trinitrate always does relieve it. The patient has been under this treatment for two weeks. In that time she has improved objectively. She has gained weight and her general appearance is much better than before.

We have under observation at this time one other case. The patient is a man, aged 32 whose gallbladder was removed elsewhere in 1927. Since that time he has suffered attacks of very severe pain in the right

upper abdominal quadrant at intervals of months, weeks or days; the attacks have lasted from fifteen minutes to eight hours. It was found very early that morphine would not relieve the pain, which was so severe that at times the patient would take 12 grains (0.77 Gm.) of sodium amytal and a pint (about one-half liter) of whisky. After administration of morphine, one-sixth grain (0.01 Gm.), as a test, cramping epigastric pain developed and gradually became more severe; later it became excruciating. An ampule of amyl nitrite was broken. After inhaling the fumes the man obtained immediate and complete relief. In ten minutes pain began to return in a mild form; one-hundredth grain (0.0006 Gm.) of glyceryl trinitrate brought relief after five minutes. In one hour pain returned; in five minutes it was again relieved by administration of glyceryl trinitrate; following this pain did not return.

#### SUMMARY

Administration of morphine produces a rise in pressure in the common bile ducts of patients whose gallbladders have been removed. This rise in pressure was accompanied by pain in one case. Periodic rises in pressure, with pain, have been demonstrated independent of the effect of morphine. Amyl nitrite and glyceryl trinitrate relieve the pain and pressure produced by morphine. Roentgenograms of the biliary tree can be made easily if a patient's gallbladder has been removed and drainage by T-tube is in progress. After proper preparation, a fluid that is opaque to roentgen rays can be injected through the T-tube; then the roentgenograms are made.

## STOMATITIS DUE TO SENSITIZATION TO DENTAL PLATES

HERBERT RATTNER, M.D.  
CHICAGO

It is not generally recognized either by physicians or by dentists that an irritant stomatitis may result in a susceptible person from sensitization to materials in dental plates, particularly the newer synthetic substitutes for rubber plates. Three such cases have recently come to my attention:

CASE 1.—Mrs. T., aged 60, formerly a nurse, for years had worn full upper and lower plates made of vulcanite. They had never been entirely comfortable, apparently because of a poor fit, but the discomfort at most was never sufficient for her to do anything about it. Three years ago she had new plates made of a substance said to be hocolite. She wore them with complete comfort for three months. Then there developed burning tongue and shortly after that a peculiar salty taste accompanied by slight increase in salivation. The symptoms were always more severe at the end of the day, to improve over night when she did not wear the plates. But the condition became progressively worse, so that when she was seen in November 1935, in addition to the severe burning tongue and the salty taste she complained that the entire mouth was sore, including the gingivae, the buccal mucous membranes, the floor of the mouth and the palate. The lips felt dry and she suffered from nausea, frequent eructations and, as she expressed it, "a weak feeling in the stomach." At the end of the day there would be a thick glairy discharge from the mouth.

She had been assured by her dentist that there were no mechanical imperfections in the dentures to account for the symptoms, and repeated examinations by physicians also failed to reveal any cause for the symptoms.

On examination there was a diffuse inflammatory reaction of the mucosa of the entire oral cavity from the vermillion

border of the lips to the pharynx. There was increased redness, very slight swelling and considerable serous exudate. The floor of the mouth and the buccal mucous membranes were involved to a lesser degree. The tongue was slightly enlarged. There were no ulcers or necrotic areas, and the vermillion surfaces of the lips were dry but not cracked.

The past history revealed that on one occasion in childhood the patient had had urticaria. To her knowledge there were no other indications of allergic diseases in herself or in other members of her family.

The sequence of symptoms beginning shortly after the wearing of a new denture suggested that the patient might be sensitive to something in the plates, especially since there were no other phenomena either medical or mechanical to account for the symptoms. A patch test was performed by strapping the plate to her arm, on the inner surface where the skin is thin. Forty-eight hours later there was an area of vesicular dermatitis on the site, which, as is shown in the illustration, was a mirror image of the plate in both size and shape. The same plate was then strapped to the skin of two other persons without producing a reaction. Within one week after she stopped wearing the plates there was a very striking improvement in both the stomatitis and the gastric symptoms. By the second week she was able to take fruit juices and spicy foods, which for the past two years she had been unable to tolerate. When some weeks later, just for a clinical test, she wore the plates again, there was a recurrence of all the symptoms within four hours. The patient continued to have slight burning of the tongue, much less however than with the original plates. Examination revealed a hypochromatic anemia, no free hydrochloric acid in the gastric contents, and slight atrophy of the tongue. A patch test with vulcanite was negative, with the original dentures it was again positive, and on wearing them there was again a recurrence of acute stomatitis.

CASE 2.—Mrs. M. C., aged 62, complained of burning tongue of about four years' duration. Her dental plates were also said to be made of hecolite, and she had worn them only a short time before the burning tongue began. The burning was intermittent in character and variable in severity. Usually she experienced the burning sensation only on the tip or sides of the tongue. Spicy foods aggravated the discomfort, and as with the first patient the symptoms were worse at the end of the day, and physicians and dentists had been unable to account for the symptoms. A patch test with the plate strapped to the arm produced a severe vesicular reaction within twenty-four hours. A change to vulcanite plates afforded decided relief from burning tongue within a relatively short period.

CASE 3.—A man, aged 50, had worn vulcanite plates with comfort for several years. The upper plate was accidentally broken and a triangular patch had to be inserted, just proximal to the central incisors. The patch was made apparently of one of the newer base materials that are used as a substitute for vulcanite. Within four days he felt burning of the tip of the tongue, and after a few days the area became red. Both symptoms and inflammation disappeared over night when the plate was not worn. The area of redness on the tongue was triangular and of the same size as the new patch on the plate, and it was situated where the tongue touched the patch—obviously a "contact" glossitis. His dentist could not find any mechanical fault to account for the symptoms, and because of the experience with the two previous cases it was thought that this was another case of sensitization to dental plates. A patch test on the arm made with scrapings from the insert in the plate, however, was negative. The negative test here may mean simply that in this patient the sensitization is confined to the tongue, a localized sensitization, or the inflammation of the tongue may be due to chemical irritation.

#### COMMENT

The cases were a new experience to me and when I casually mentioned it to several colleagues, medical and dental, it was apparent that the condition was new to them. In a fairly thorough search of the pertinent literature I was able to find an account of but one similar case, that of Lindsay, quoted by Lain.<sup>1</sup> Prinz

and Greenbaum<sup>2</sup> also state that they have seen hypersensitiveness of the oral mucosa following the use of dental plates made of the newer base materials.

It is not unknown for sore mouth to develop after vulcanite plates have been worn, although it occurs relatively infrequently. "Rubber sore mouths" have been known ever since vulcanite has been used in plates,<sup>2</sup> and the subject has been fully discussed in dental literature. It is the consensus that the sore mouths are due probably to a combination of factors. The plate resting on the mucous membrane acts as a foreign body, which during mastication and speech mechanically irritates the mucous membrane, especially if it "rides the mucosa." There is as a result abnormality in the circulation of the mucous membranes and in its secretions. In addition the plates are not self cleansing, so that there may be an accumulation of food debris, and they are poor conductors of heat. Other factors, such as imperfect vulcanization causing porosity of the plate, and the possible poisonous action from chemicals used in the pigments, are also thought to be important in the development of sore mouths from dental plates. That dentists have been able to overcome most of these objections is evident from the fact that probably

Positive patch test from dental plate.

millions of people wear dental plates without discomfort. These and mechanical faults are usually sought in cases of sore mouth, but that the condition might be due to sensitization to the materials in the plates is not generally considered.

When the first patient was seen, a letter was addressed to the manufacturers of the denture material stating the facts and asking for information that might help to ferret out the irritating ingredient. They answered to the effect that there was nothing in the material that in any manner would cause chemical irritation, and they suggested that the symptoms were probably due to mechanical pressure. This, of course, does not account for the positive reaction to the patch test on the arm, which is made even more significant by the negative tests on two control patients. The newer base materials used as substitutes for vulcanite are made up essentially of cellulose treated with various chemicals and then combined with pigments, fillers and other substances. Others consist of phenol-resin compounds containing phenol, formaldehyde, ammonia, coloring matter and fillers. As Prosser White<sup>3</sup> has pointed out, coloring with chrome, polishing with lime

1. Lain, Everett: Chemical and Electrolytic Lesions of the Oral Cavity Produced by Metallic Dentures, *Arch. Dermat. & Syph.* 25: 21 (Jan.) 1932.

2. Prinz, Hermann, and Greenbaum, S. S.: Diseases of the Mouth and Their Treatment, Philadelphia, Lea & Febiger, 1935, p. 215.

3. White, R. P.: The Dermatogoses, ed. 4, London, H. K. Lewis & Co., Ltd., 1934, p. 264.

and the numerous liquids used for the solution of cellulose can be ample sources of injury to the skin and, of course, to mucous membranes. The processes used in the manufacture of the various synthetic base plates are trade secrets, but judging from what is known about them it is quite likely that at some step in the process a compound is formed or an ingredient is used which might be irritating to the tissues in the mouth of a susceptible person. The cases herewith reported would seem to indicate so, for in none of them could the symptoms be accounted for on the basis of mechanical faults, infections or other medical factors, and, so far as could be determined, irritants such as dentifrices could also be eliminated as etiologic agents.

#### SUMMARY

Three cases of stomatitis followed the use of dental plates. In two of the cases there were strong reactions to patch tests on the skin made with the denture material. The dental plates, synthetic substitutes for vulcanite, are made by processes that are trade secrets, but sufficient is known of their composition to indicate that they can readily irritate susceptible tissues. The stomatitis in these cases is thought to be due to sensitization to the materials in the dental plates.

### PERINEAL TESTICLE

MEREDITH F. CAMPBELL, M.D.

NEW YORK

Failure of the testicle to reach its proper destination in the scrotum is the commonest important anomaly of the spermatic tract. As a rule the improperly descended testicle is located at some point along the normal course of descent (abdominal, inguinal or high scrotal) but in some instances the organ is ectopic or aberrant. The ectopic gland may be (a) interstitial (lying anterior to the aponeurosis of the external oblique muscle), (b) femoral or crural (lying in Scarpa's triangle), (c) penile (overlying the pubic bone), (d) perineal and (e) transverse (fig. 1). In the last instance the two testes descend through the same inguinal canal. The present discussion concerns only perineal ectopia; three instances recently observed in children are reported.

#### ETIOLOGY

**Incidence.**—Perineal testicular ectopy is an unusual observation. Although the reported incidence of improperly descended testicle varies from 1.02 per cent in 108,000 men<sup>1</sup> to 3 per cent in 14,410 boys under 14 years of age,<sup>2</sup> Burdick and Coley<sup>3</sup> did not encounter a perineal testicle in 537 cases of cryptorchidism. It was not observed in 18,000 autopsies in males whose postmortem records I<sup>4</sup> studied for uropathy. Nor has a case of perineal testicle been seen in more than 36,000 admissions to the urologic service of Bellevue Hospital. On the other hand, Eccles<sup>5</sup> found five cases in 936 undescended testicles; Robertson<sup>6</sup> recently reported an operative case in a 3 months old boy. There are

ninety-nine instances recorded in the literature to date. Curiously, in a moderate size general hospital I saw three cases during a period of twenty months.

**Embryology.**—The mechanism by which the testicle normally migrates from the high intra-abdominal position of early fetal life to the bottom of the scrotum is unknown. The oft repeated conception of downward

Fig. 1.—Sites of abnormal descent of the testicle.

traction of the testicle by the gubernaculum is still *sub judice* for, as Hunter<sup>7</sup> has shown, the testis of the newborn together with the fascial coverings may be lifted out of the scrotum without tearing anything but a little superficial connective tissue. Lockwood's<sup>8</sup> theory of

Fig. 2 (case 1).—Left perineal testicle in 11 year old boy. Indwelling catheter in urethra following transurethral resection of congenitally hypertrophic verumontanum.

a multitailed gubernaculum, the tails of which pass from the testicle to the bottom of the scrotum, the pubis (penile), the spine of the ischium (perineal) and Scarpa's triangle (femoral or crural), has been adduced by some to explain testicular ectopy; i. e., the testicle goes in the direction of the strongest pull. Suggestively

commending this theory was the observation in my two operative cases that the strong gubernaculum passed from the lower pole of the testicle to the spine of the ischium and firmly withheld the organ in the perineum. Yet Sønneland<sup>9</sup> discards Lockwood's notion and believes that, once the testicle has descended through the external inguinal ring, the action of the gubernaculum is no more than passive. If the gubernaculum is inadequate or breaks at this point, the testicle descends along the line of least resistance and becomes ectopic. The anomalous descent occurs between the same fascial planes (superficial or Camper's and deep or Scarpa's) that guide urinary extravasation. Some writers believe that a tight scrotal aperture above (the so-called third inguinal ring<sup>10</sup>) may deflect the descending testicle. This observation was striking in both the boys on whom I operated.

#### PATHOLOGY

The perineal testicle is subject to the same unfavorable factors as are organs in inguinal or other forms of maldescent. If the anomalous condition is permitted to persist, atrophy and loss of fertility of the gland are certain. The organ is subjected to ill borne trauma and, according to Dean,<sup>11</sup> the improperly descended testicle is 200 times more likely to become the site of a malignant growth than is a normally descended gland.

#### SYMPTOMS AND DIAGNOSIS

Presence of the testicle in the perineum and its corresponding absence from its normal scrotal position is both the commonest presenting symptom and the diagnostic criterion. The organ may be relatively insensitive (when greatly atrophied) or it may be the site of intermittent or constant dull or acute pain. Epididymitis in a perineal testicle has been reported.<sup>12</sup> By palpation the relative degree of testicular atrophy can be determined by comparison with the normal mate. In any patient with cryptorchidism the perineum should be examined.

Sometimes, as illustrated by cases 1 and 3, the testicular anomaly may be but one of a number of congenital developmental errors. Moreover, it is observed that in about 35 per cent of cases of genital anomaly the upper urinary tract also is anomalous (e. g., case 1).

#### TREATMENT

Treatment is necessarily surgical. There is no preventive treatment. For obvious reasons hormone therapy (pregnancy urine extracts such as antuitrin-S and follutein), which is often so valuable in inguinal and abdominal testicular maldescent, is of no help in perineal or any other form of testicular ectopia. The spermatic cord is long enough, but the gland has descended into the wrong channel and can be properly placed only by surgical methods.

*Time for Operation.*—Unless the ectopic gland is producing symptoms, operation should be withheld until after the third birthday. It is advisable, however, to transplant the testicle to its normal scrotal location soon thereafter, and in all events before the boy starts riding a bicycle or in active play runs the risk of a straddle injury.

*Operation.*—Through an incision from 3 to 4 cm. long, the external inguinal ring and the upper portion of the ectopic spermatic cord are exposed. The incision

begins just above the level of the external ring and extends downward in the scrotofemoral fold toward the ectopic gland. Between the superficial and the deep perineal fascial layers the testicle will often be found firmly anchored by its gubernaculum, perhaps most frequently to the spine of the ischium. The gubernaculum is now divided so that a generous segment remains for suture to the depth of the new scrotal pocket. The cord, which will be found of ample length, is mobilized to the external inguinal ring and is examined for a hernial sac. Yet congenital hernia is not common in perineal testis. The tunica vaginalis is now everted behind the testicle. This prevents traumatic (surgical) hydrocele, which is almost certain to follow if the precautionary eversion is not performed. An adequate pocket is made in the scrotum to receive the testicle. The pocket is turned inside out and to its depths the gubernaculum is stitched with fine chromic gut. Due care must be observed that in transplanting the testicle to the scrotum the cord is free of torsion. The testicle having been properly placed, it is well to close the fascial ring of the upper part of the scrotum with two or three fine chromic sutures to keep the testicle down in the scrotum. In other words, the so-called third inguinal ring is reformed. The wound is now closed without drainage.

In my two operative cases I anchored the gubernaculum with a transfixion ligature of unabsorbable suture, which was then passed out through the bottom of the scrotum. This suture was tied to a small rubber band, to which in turn was tied a suture passed through the skin of the lower inner thigh. These sutures were tied to the interposed rubber band under sufficient tension to cause mild traction to be exerted on the testicle, a maneuver adopted from Cabot's technic in the correction of undescended testicle. In from three to six days the traction suture pulls out, but during this time the testis has become well adherent to the bottom of the scrotum and the cord has been kept at full length.

Should hernia coexist, herniotomy also is performed.

#### REPORT OF CASES

CASE 1.—H. S., aged 11 years, was referred by Dr. Henry Larson of Morristown, N. J., Oct. 6, 1934, because of persistent pyuria, repeated gastro-intestinal disturbances, and failure to gain. A thorough urologic examination at Mountsinle Hospital revealed advanced infected hydronephrosis (*Bacillus coli* and *Staphylococcus aureus*) of the lower half of a reduplicated left kidney; a stricture at the vesical junction of the ureter to the diseased segment was the important accessory cause of the renal pathologic condition. Other discoveries of urologic importance included a congenital stricture (7 F.) of the urethra at the penoscrotal angle, congenital hypertrophy of the verumontanum, spina bifida occulta, six lumbar vertebrae, a residual urine which varied between 5 and 7 ounces (150 and 210 cc.), and a left perineal testicle. The gland felt normal and was situated just to the left of the midperineum (fig. 2). Other physical appearances were normal.

The boy also suffered a curious hematologic anomaly which made it necessary to type fourteen members of his blood group (Moss III) before one was found whose cross agglutination test was negative after thirty minutes. Yet when transfusion was done an almost fatal reaction occurred.

Left ureteroheminephrectomy was performed October 12. In three and a half weeks the boy went home, to return November 13, at which time the left perineal testicle was put in its normal position in the scrotum and the infravesical obstructions were eradicated.

With the patient in the lithotomy position and under nitrous oxide-oxygen anesthesia, the operation described under surgical treatment was carried out. The ectopic spermatic cord was mobilized from the external inguinal ring downward and finally

9. Sønneland, S. G.: *Ann. Surg.* 80: 716 (Nov.) 1924.

the testicle was separated from its perineal attachment of the gubernaculum to the spine of the ischium. It was noted that the gubernaculum was unusually well developed and extremely tense. The tunica vaginalis was now incised and everted behind the testicle, where it was held by a fine mattress suture. The testicular mesentery was extremely long and permitted the epididymis to hang freely as a wormlike structure. The operation was then completed according to the previously described technic. The urethra was dilated to 18 F. With my miniature resectoscope and the high tension cutting current the greatly hypertrophied verumontanum was subtotally resected. There was mild bleeding; indwelling catheter drainage (12 F.) was established. Immediate convalescence was uneventful, but on the third day and soon following the removal of the indwelling catheter the patient had a chill, the temperature rose to 105.4 F. and the pulse rate increased from 90 to 154 beats per minute. The catheter was reinserted for two days; the acute reaction subsided within twelve hours. In two days the temperature was normal and on the sixth day the traction suture cut through and released the testicle. The boy returned home eight days after the operation.

Postoperatively the urethra has been periodically dilated and the urine has been sterilized with large doses of methenamine (from 60 to 75 grains [3.8 to 4.8 Gm.] per day) and of ammonium chloride. Of the latter, 200 grains (13 Gm.) a day was necessary in order to obtain the desired urinary acidity of pH 5.5. The urine has been sterile for more than a year and there has been no residual urine. The testicle previously ectopic is now normal in position and to palpation.

This case admirably illustrates the startling number of urogenital anomalies with which an individual may be born. It also indicates how, by multiple step procedures and with the application of modern methods of diagnosis and surgical treatment, many of these congenital handicaps (some of which are potentially fatal) can be eradicated. It is of further interest that during the six months following ureteroheminephrectomy the boy gained 24 pounds (11 Kg.). Repeated gastro-intestinal disturbances and failure to gain had been important symptoms in the past history and obviously resulted from renal toxemia.

CASE 2.—J. B., aged 7 months, admitted to the urologic department of Mountinside Hospital in January 1934, had a perineal testicle on the left side. The boy's history and physical examination were otherwise negative. The ectopic gland was of normal size and was situated in the posterior perineum slightly to the left of the midline. Because of his tender age, operation was deferred. The patient was again seen Sept. 23, 1935, at the age of 24 months. Conditions were the same as on the first examination. A questionable left hernial impulse was obtained.

September 26 the perineal testicle was replaced in the scrotum in a manner identical with that previously described. No hernia was found. The traction suture pulled out on the third day. The boy left the hospital one week after operation and when seen four months later presented a most satisfactory surgical end result.

CASE 3.—S. T., aged 14 years, was seen in the urologic department of Mountinside Hospital, Aug. 29, 1935. The right testicle was undescended at the external inguinal ring, where there was a moderate hernial impulse. The left testicle was found in the midperineum and when palpated appeared to be of normal size. Operation was advised, a Torek procedure to be carried out on the right side and the previously described operation for perineal testicle on the left. Because of parental objection this has not yet been accomplished.

#### SUMMARY

Perineal testicle is an unusual genital anomaly. The embryologic etiology is unknown. Diagnosis is made by inspection and is confirmed by palpation. The treatment is surgical and consists of placing the ectopic organ in a newly made pocket in the scrotum. Unless this is done the ectopic organ is abnormally subjected

to trauma; atrophy and isolateral sterility are almost certain. Endocrine therapy is ineffectual in correcting this variety of maldescent. There should be neither surgical morbidity nor surgical mortality.

140 East Fifty-Fourth Street.

#### THE PRESENT STATUS OF OUR KNOWLEDGE OF HEREDITY AND CANCER

C. C. LITTLE, Sc.D.

BAR HARBOR, MAINE

During the past thirty years, evidence derived from biologic experimentation in the laboratory has yielded considerable information concerning the nature of the constitutional or hereditary factors which predispose certain animals to cancer and which make others unlikely to develop it. As long ago as 1907-1910, Tyzzer, J. A. Murray and Bashford had pointed out that, in mice, the progeny of females which developed spontaneously cancer of the breast were more apt to form this type of neoplasm than were animals not so descended. Slye in a long series of papers demonstrated, as did Loeb and Lathrop, that different families and strains of mice showed, in each case, a more or less characteristic degree of cancer function. None of these investigators had available for experimentation strains in which genetic homogeneity had been attained. As a result, the genetic variables that were present prevented an exact test of the nature of the process of transmission from one generation to another of the tendency to form cancer.

The key as to how to obtain strains that were genetically homogenous first became known to geneticists by the work of Johannsen and of Jennings in 1909. It was not, however, until another decade had passed that the production of such homogenous strains became generally recognized as an essential step before the genetics of any such a phenomenon as cancer could be investigated. The process by which genetic uniformity is produced is one of rigid inbreeding of own brother to sister or of progeny to parents. King's well known work with inbred selected strains of rats did much to show that the process could be outstandingly successful and proved the incorrectness of such assertions as that of Slye to the effect that "continued inbreeding eliminates any strain."

Beginning in 1909 I had selected for intensive inbreeding the descendants of a single pair of mice the color of which was dilute brown. This strain has been continued since that date. As time passed other unrelated inbred strains have been developed. In some of these the incidence of cancer of the breast runs as high as from 85 to 100 per cent in breeding females 14 months of age or older. In others cancer of the breast occurs very rarely, perhaps in 0.1 per cent or less. Other types of neoplasm are also obtained in characteristic amount according to the particular strain used.

There are three levels at which the genetics of cancer can be investigated. One of these deals with the genetic behavior of animals in relation to transplants of various tumors which originated spontaneously either within a given strain or in some unrelated strain.

The genetics of susceptibility or nonsusceptibility to transplants of various tumors was successfully worked

out by Bittner, Cloudman, Strong and myself during the period 1914-1936. It has been reviewed by Haldane and by Bittner.

Whether a given animal will grow a certain tumor on transplantation depends on the degree of biologic similarity between the host and the tissue of the tumor used for transplantation. The degree of biologic resemblance is chiefly determined by mendelian genes. The number of genes involved varies in each case, being as low as one in some cases investigated and as high as twelve or fifteen in others. This general conclusion is based on the genetic analysis of more than thirty different spontaneous tumors and on more than 25,000 individual transplantations.

By 1928-1929 there were on hand a sufficient number of inbred strains of mice to make the beginning of work on the genetics of spontaneous tumors seem desirable. Strains high in cancer incidence were crossed with low cancer strains in various ways and the hybrids of different generations were observed for cancer incidence. All animals were examined after death and all suspicious nodules were sectioned and diagnosed.

With the coming to maturity of females that were first generation hybrids between cancer and "non-cancer" strains, a test was provided for Slye's widely publicized hypothesis that the incidence of all spontaneous cancer is due to a single mendelian recessive hereditary factor. The presence of a large number of cases of cancer in the first generation hybrids has definitely disproved this theory, which even on Slye's own data I had shown (1928) to be of extremely doubtful validity.

At the same time (1933-1935) results have been published which establish certain general principles for future guidance. Without detailed consideration of the various publications to which reference will be made, these principles and conclusions may be very briefly summarized as follows:

1. That the genetic constitution of an animal is of prime importance in determining the likelihood of its having cancer of the breast is shown by outcrosses between high and low cancer strains.

If a strain in which the incidence of breast cancer among virgin females is high (approximately 50 per cent) is crossed with a low cancer strain, the amount of breast cancer appearing among virgin females of the first hybrid generation is largely dependent on the strain from which the female ancestor is derived.

Thus if a "high" strain female is crossed with a "low" strain male the incidence of breast cancer in the virgin female hybrids is approximately 39 per cent.

If, on the other hand, a "low" strain female is crossed with a "high" strain male the incidence of breast cancer is only 6 per cent.

This difference holds good for the second hybrid generations as well as for the first, in a large number of animals (over 1,200).

This type of inheritance is nonmendelian and is unique among animals. It follows the maternal line and definitely establishes the existence of genetic influences outside the chromosomes.

2. Studies of a preliminary nature have shown no such unusual behavior of genetic factors underlying the incidence of such tumors as lymphosarcomas. The genetic influences in this case seem to be equally derived from either the male or the female line. This is characteristic of the normal type of mendelian inheritance, which depends on the chromosomes. The distinction

between cancer of the breast and such types as lymphosarcomas thus seems fundamental. As far as the present evidence is concerned there seem to be many genetic factors involved in the spontaneous incidence of sarcomas of various types.

3. Blockage of the nipples on one side of the body resulting in no drainage during lactation seems to make the blocked side a more frequent site of breast cancer among females derived from a high cancer stock. It fails entirely to produce cancer in females derived from a low cancer stock. This is a clear proof of the relative rôles of constitution on the one hand and irritation due to blockage on the other. The former is basic (Green and Fekete).

4. There is some relationship between the amount and function of mammary tissue and its tendency to form a cancer in those inbred strains of mice which are high in cancer incidence. Thus virginity delays the appearance of cancer of the breast and also actually reduces the amount of it appreciably (W. S. Murray).

5. The presence of ovarian secretion is a factor in influencing the amount of mammary development and consequently affects its ability to act as the site of cancerous changes.

6. For this purpose it is not necessary to derive the ovarian secretion from a high cancer strain individual. Thus ovaries from a low cancer strain transplanted in castrated animals of a high cancer tendency, or even injections of theelin in such animals, will allow cancer of the breast to develop in some cases (J. M. Murray, Lacassagne, Little, unpublished data).

7. Absence of testicular secretion caused by castration after 4 weeks of age is not sufficient to allow males that are brothers of females in a high cancer stock to develop cancer of the breast. On the other hand, when such castrated males receive and maintain transplanted ovaries (W. S. Murray) or injections of theelin (Lacassagne) they may develop cancer of the breast.

8. The technic of keeping the genetic constitution constant and varying the ovarian and mammary functions has given sufficient information to make it possible to recognize that the degree and extent of those functions is a factor of the internal environment of the individual which may importantly affect the incidence of breast cancer.

9. The technic of keeping ovarian and mammary function constant and varying the genetic factors has shown that hereditary transmission of constitutional influences plays a basic rôle in the incidence of cancer of the breast.

It may be pointed out in conclusion that the accepted method of making human matings, viz., by uncontrolled outcrossing combined with the inadequate records and small numbers of progeny which commonly are encountered in human families, militates against the practical use of controlled heredity as a means of reducing the incidence of cancer in man. This, however, does not prevent the genetic approach to the problem in the laboratory and the use of controlled homogeneous inbred strains of mice from being extremely favorable material for pure scientific research in the nature and cause of cancer.

## Clinical Notes, Suggestions and New Instruments

### A CASE OF CONTACT DERMATITIS PRODUCED AT A DISTANCE BY THE SENSITIZING AGENT

JOSEPH B. BIEDERMAN, M.D., CINCINNATI

In the classification of skin diseases, contact dermatitis or dermatitis venenata appears as a clinical entity, separate from the more inclusive term eczema. The chief reason advanced for this separation is that in contact dermatitis it is necessary to have actual physical contact between the causative agent and that portion of the skin involved. The case herewith presented demonstrates that contact dermatitis or dermatitis venenata may be produced by a sensitizing agent acting at a distance.

C. M., a man, aged 29, a truck driver, complained of a dermatitis present on the extensor surfaces of both hands and both feet. This had been present for the past six months. The patient stated that one and one-half years before he had had a similar ailment, which lasted for three months and disappeared. He had been driving a truck for six years, but only for the past one and a half years had he noted an eruption. At that time he took a trip into the country and two

bottles. Fifteen minutes later the Ethyl caused itching and burning, and the area of skin covering the open end of the bottle was reddened. Forty-five minutes later X-70 and Renown both showed the same effect. All the involved areas also showed the presence of blisters about six hours after contact with the gasoline. The itching and eruption caused by X-70 and Renown practically disappeared in twenty-four hours. That caused by Ethyl persisted for forty-eight hours. My arm, used as a control, was entirely normal. This reaction could very well explain the eruption on the dorsum of both hands, but could this explain the involvement of both feet? So far as the patient knew, his feet had not been in contact with gasoline. He was advised to discontinue work, and again his skin cleared. When he resumed his former work the lesions reappeared after an interval of three months.

The possibility presented itself that the dermatitis on the back of the feet might be due to a localization there of the excess gasoline absorbed elsewhere.

The following experiment was then performed: Each forearm was exposed daily for forty-five minutes to the vapors given off from the three brands of gasoline he used, and the results are noted in the accompanying table. The first day, fifteen minutes after the application of the ethyl gasoline, an itching and redness was noted on the patient's arm. Forty-five minutes after application all three areas itched to such an

weeks later the eruption on both hands and feet disappeared. It had been present for ten weeks previously. One year before admission he again began to drive a truck and six months later the eruption reappeared on the dorsum of the hands, where it remained for three months and then involved the dorsum of both feet. He complained of itching and burning of the areas involved, which were worse while he was at work or after he worked on his own automobile. Occasionally the entire body would itch and burn, but most of the symptoms were limited to the hands and feet. His past history was negative for any allergic manifestations. His family history revealed that his mother had had hay fever and his father asthma.

Physical examination was not remarkable except for the skin lesions present on the dorsum of both hands and both feet. The eruption was characterized by scales, fissures and marked reddening. There were also some areas oozing a thin watery material.

The urine and blood count were within normal limits, and the blood Wassermann test was negative. Extensive skin tests with the intracutaneous method were all negative. The usual common materials used in the patch tests were also negative.

He was then told to bring a sample of everything he handled while at work. Everything tested was negative. He mentioned that he was in the habit of washing his hands with gasoline when they were very dirty. He was told to bring a sample for the purpose of testing of each kind of gasoline he used. He brought Ethyl, X-70 and Renown gasolines. Each of these was placed in a separate 1 ounce glass container and the flexor surface of his forearm was placed over the openings of these

extent that the patient asked to have the experiment stopped. My forearms used as a control were not involved. Five hours later the redness was followed in another hour by blisters. The lesions caused by X-70 and Renown gasolines practically disappeared after twenty-four hours, while the lesions due to Ethyl gasoline lasted for forty-eight hours. The second day the same procedure was carried out on the other forearm, with practically the same results. This experiment was performed daily with the same results but using different clear spots on alternate arms until the eighth day, when an eruption appeared in the popliteal areas and he complained of "feeling miserable over his entire body" about the same time. He also complained simultaneously of a feeling of fullness in the joints. Nevertheless he asked to have the experiment continued. On the ninth, tenth, eleventh and twelfth days the same procedure was followed, except that the gasoline was applied twice a day instead of once. Until this time I would place the gasoline on alternate arms. When I alternated thus the lesions would disappear (except those caused by Ethyl) when I was again ready to use the same arm. On the twelfth day, however, the healed areas on the two arms erupted simultaneously with those on both legs. One day later, although no more gasoline vapors were contacted, the eruption spread over the entire body. The popliteal areas, the flexor surfaces of the forearms, and the axillae were most extensively involved. Fifteen minutes before the generalized eruption occurred, the patient stated that he felt as though needles were pricking his bones. Within two months the lesions had healed. He was told to avoid contact with gasoline and has been free from symptoms except on two different occasions when he has had definite exposure to gasoline.

This case is reported to demonstrate that it is possible to have a so-called contact dermatitis caused by the responsible agent acting at a distance from the skin area involved. These studies suggest that after repeated exposure to a sensitizing agent the latter can be absorbed and affect other areas of the skin not in direct contact with the offending agent, whereas a smaller quantity may cause only a local lesion.

Doctors Building.

#### TRAUMATIC DELTOID PARALYSIS TREATED BY MUSCLE TRANSPLANTATION

WILLIAM DONALD DAVIDSON, M.D., EVANSVILLE, IND.

Flaccid paralysis of the deltoid muscle may result from poliomyelitis, obstetric paralysis or traumatic injury of the circumflex (axillary) nerve. Various operative procedures have been proposed to relieve this severe lesion. Of these the transplantation of the origin of the short head of the biceps from the coracoid process, and the origin of the long head of the triceps from the inferior margin of the glenoid cavity, to the tip of the acromion, as proposed by Dr. Frank Ober,<sup>1</sup> has been the most successful.

The operation was first used to relieve deltoid paralysis resulting from infantile paralysis, but Dr. Ober has since extended its use to those cases resulting from obstetric paralysis. This report is to present a case of deltoid paralysis, caused by a traumatic lesion of the circumflex nerve, in which this operation was successfully used.

#### ANATOMY

The circumflex nerve arises from the posterior cord of the brachial plexus and consists of fibers from the dorsal divisions of the fifth and sixth cervical nerves. It passes downward and outward from behind the third portion of the axillary artery and over the outer border of the subscapularis muscle to enter the quadrilateral space, where it lies beneath the posterior circumflex artery and vein. It then turns about the posterior and external surface of the surgical neck of the humerus to end within the deltoid muscle. The nerve consists of two main bundles, the larger medial funiculus supplying the teres minor and a part of the deltoid, after which it passes under the deltoid and around the lower part of the posterior border to supply the skin over the long head of the triceps and the lower two thirds of the posterior part of the deltoid. The lateral branch supplies the remainder of the deltoid and gives off an articular branch to the shoulder joint.

This exposed position of the circumflex nerve makes it particularly liable to injury. It may be easily torn or compressed in fractures of the surgical neck of the humerus or in dislocations of the shoulder joint, or it may be contused by blows on the shoulder. If paralysis of the circumflex nerve results, loss of motor power to the deltoid and teres minor muscles results in an inability to abduct the arm. Elevation of the arm to a degree less than a right angle may be accomplished by the supraspinatus muscle.<sup>2</sup> There is also a loss of sensation over the cutaneous distribution of the nerve, involving the skin over the long head of the triceps and the lower posterior part of the deltoid.

#### REPORT OF CASE

M. K. K., a student nurse, aged 20 years, has always been very athletic. On the first day of her annual vacation, Aug. 3, 1935, she was in swimming. A diver struck her forcefully on the left shoulder. On the following day the entire left shoulder region was so painful that motion was impossible. Motion gradually came back, and by the time she returned to duty she could abduct the left arm to 80 degrees with the elbow flexed to a right angle. She continued on duty until September 30, when her room-mate noticed that the left shoulder region was markedly flattened. She was seen on the following day and stated that there was a continuous dull ache in the left shoulder and that she did not possess the full use of the arm. Physical examination at that time showed a marked atrophy of the left deltoid, in contrast to the excellent development of the neighboring muscles. This atrophy caused undue prominence of

the acromion and coracoid process. The capsule of the shoulder joint was relaxed three-fourths inch. All motions of the arm except abduction and forward raising were normal. With the elbow extended, she was able to abduct the arm 30 degrees. When the elbow was flexed at this point, the long head of the biceps aided the supraspinatus, and abduction was possible to 80 degrees. Sensory examination showed complete anesthesia over the complete cutaneous distribution of the circumflex nerve. Electrical stimulation showed an absent response of the deltoid muscle to the galvanic current. Neurosurgical consultation was obtained and the diagnosis of a traumatic lesion of the circumflex nerve confirmed. The consultant did not recommend exploration of the nerve. The left arm was placed on a platform splint, holding the shoulder in 90 degrees abduction and 10 degrees forward of the coronal plane. Daily sinusoidal current and diathermy treatments, together with massage and exercises, were begun.

The possibility of muscle transplantation had been discussed with the patient. Toward the latter part of November she requested operation, saying that the shoulder ached continually and that she was afraid that she would not be able to resume training. December 2, four months after the injury, operation was performed. The short head of the biceps and the long head of the triceps were freed subperiosteally from their origins and transplanted into a shark mouth incision osteotomized in the tip of the acromion. At the time of operation, the deltoid and teres minor were found to be completely flaccid. The transplanted muscles were exceptionally large and of excellent quality. Special care was taken in closing the deep fascia. At the conclusion of the operation, the humeral head was quite firmly held in the glenoid cavity. The arm was replaced on the platform splint. On the third postoperative day, the patient stated that the dull dragging sensation in the shoulder had disappeared. Muscle reeducation was begun on the fourteenth postoperative day, at which time the transplants could be felt to contract. The following day, with the arm gently supported, she could raise the arm 10 degrees from the splint, while on the eighteenth postoperative day she could raise it above her head. At the end of six weeks she could raise the arm from her side to above her head or abduct it through the same range. Abduction was possible using each transplant separately, as well as by their combined action.

She returned to light duty at the end of eight weeks, wearing the splint during class hours and at night, and returned to full floor duty at the end of twelve weeks. At the time of this report, it has been seven months from the time of the original injury and fourteen weeks since operation. She has full functional use of the left arm and is performing regular nursing duties in a satisfactory manner. Paralysis of the circumflex nerve is still complete, as evidenced by the undiminished area of skin anesthesia and the absence of reaction of the deltoid to electrical stimulation. On being shown a recent report of a case in which spontaneous recovery of a paralyzed circumflex nerve began after seven months,<sup>3</sup> she remarked that she still was quite satisfied to have had the operation, since she could do all her work and did not have to wear a splint.

#### CONCLUSION

This case is reported as evidence that transplantation of the short head of the biceps and the long head of the triceps to the tip of the acromion is of value when deltoid paralysis results from trauma to the circumflex nerve, as well as in cases resulting from poliomyelitis or obstetric paralysis. The sound mechanical principle underlying this type of operation, as evidenced by ability to abduct the arm by either transplant acting separately, indicates that better function in the other types of deltoid paralysis should be obtained by this operation than by other types of muscle transplants. It is felt that, since a traumatic lesion of the circumflex nerve gives a prolonged disability and an uncertain prognosis, this procedure may be done advantageously in those cases in which time is an important factor and that it offers more hope than exploration of the nerve. If spontaneous recovery should occur, the transplants will prevent undue strain on the deltoid and check any tendency of the capsule to relax.

# RECURRENCE OF PAROXYSMAL AURICULAR FIBRILLATION AFTER PERMANENT RELIEF OF HYPERTHYROIDISM BY SUBTOTAL THYROIDECTOMY

ERNST P. BOAS, M.D., NEW YORK

This report concerns a patient with hyperthyroidism with established auricular fibrillation before operation, in whom sinus rhythm was restored following the postoperative administration of quinidine. Nineteen months after her thyroidectomy she was operated on for carcinoma of the colon. This operation was performed in three stages. Immediately after two of these operations transient auricular fibrillation developed, which subsided spontaneously after about twelve hours on each occasion. Since that time a year and a half has elapsed and the rhythm has remained regular.

A woman, aged 50, seen June 14, 1932, had had the menopause three years previously. She had been well until about a year previously, when she began to complain of increasing weakness and nervousness. She became excited very readily and noted palpitation and dyspnea on exertion. Two weeks previously during a meal, she suddenly was unable to move her right hand and her speech was altered. These symptoms lasted only a few moments. The following day she vomited. These symptoms did not recur. She had lost 7 pounds (3,175 Gm.) during the previous two months.

On examination the patient was well nourished, weighing 157 pounds (71 Kg.). There was marked tremor of the hands. There were no paralyses and all the reflexes were normal and exaggerated. The eyes were not prominent, and there were no abnormal eye signs. The thyroid isthmus was palpable but did not appear enlarged. There was no substernal thyroid. The lungs were clear. Fluoroscopy revealed moderate enlargement of the left ventricle. The first heart sound was of good quality. There were no murmurs or accentuations. The rhythm of the heart was absolutely irregular, the rate being about 120. The blood pressure was 160 systolic and 80 diastolic. The electrocardiogram revealed left axis deviation, auricular fibrillation and occasional ventricular extrasystoles. The basal metabolic rate was plus 38 per cent.

She was prepared for operation with aqueous solution of iodine and, June 27, subtotal thyroidectomy was performed by Dr. Harold Neuhof. A rather large right lobe, containing a cyst, and a small left lobe were found. The auricular fibrillation persisted and five days after operation she received quinidine sulfate. After 24 grains (1.5 Gm.) of the drug had been administered, sinus rhythm was restored. The heart rate was 64. July 12, auricular fibrillation recurred but was quickly controlled with further dosage of quinidine. Following this the heart remained regular. She lost her nervousness, gained 7 pounds and was free from symptoms. November 3 her basal metabolic rate was minus 9 per cent. Her pulse rate was 54, the rhythm was regular and the blood pressure was 160 systolic, 80 diastolic. She was seen again, Feb. 16, 1934. During the previous six months she had had occasional sticking cramps in the left lower quadrant. Five days previously these cramps became very severe and during this period there had been no bowel movement. A small mass was felt in the left lower quadrant. Roentgen examination of the colon revealed a marked constriction at the junction of the sigmoid and descending colon. There was no recurrence of the hyperthyroidism or of auricular fibrillation. Dr. Leon Ginsburg, performed a Mikulicz operation for carcinoma of the descending colon in three stages. February 17 a cecostomy for intestinal obstruction was performed. This was uneventful. March 5 the second stage of the operation was performed under spinal anesthesia. The operation lasted one hour and forty minutes. At the end of the operation the rhythm of the heart was absolutely irregular and its rate was 136. The irregularity persisted for thirteen hours, when sinus rhythm was reestablished spontaneously. During this period the temperature was normal. There was no recurrence of the irregularity until June 11, when the patient was again operated on under spinal anesthesia for extraperitoneal closure of the colon. Again the operation was followed by a short period of auricular fibrillation, which disappeared spontaneously. The rhythm has remained regular ever since and there have been no cardiovascular symptoms.

Auricular fibrillation is rarely provoked by anesthesia and operation except in patients with hyperthyroidism. Kurtz and

his associates<sup>1</sup> encountered it only once in 113 nonthyroid operations during which the patients were studied electrocardiographically, and that was in a patient with heart disease. Commonly patients with hyperthyroidism with normal cardiac rhythm before operation develop auricular fibrillation during the first two or three days following operation. The immediate increase of basal metabolism following operation has been held responsible for this phenomenon.<sup>2</sup>

Following subtotal thyroidectomy there is a spontaneous reversal to normal sinus rhythm in about 50 per cent of patients with hyperthyroidism and auricular fibrillation, and if quinidine sulfate is given to the remainder only 10 per cent of the whole group maintain their abnormal rhythm.<sup>3</sup> The refractory cases are those with an additional type of heart disease or those in which operation has been incomplete. The irregularity persists, particularly in patients with mitral stenosis.<sup>4</sup> Once normal rhythm has been established, recurrences of auricular fibrillation are rare and are due usually to recurrent hyperthyroidism or to coincident cardiovascular disease.<sup>5</sup>

The occurrence of auricular fibrillation in the course of hyperthyroidism is not a simple result of the action of the excess thyroid secretion on the heart. It is encountered most commonly in older patients with hyperthyroidism and in those who have cardiac enlargement. Several factors must be at play: a structural or chemical alteration of the heart, thyroid intoxication, and increased work of the heart.

Although my patient had a slight hypertension and some left ventricular hypertrophy there was no dilatation of the auricles, and there had never been signs or symptoms of heart failure. Auricular fibrillation in hypertensive heart disease occurs only in the presence of considerable cardiac enlargement and heart failure. Thus the hypertension cannot have caused the irregularity. Nor was there a recurrence of the hyperthyroidism. Apparently, the auricles originally fibrillating in response to a thyrotoxicosis are now so conditioned that they revert to this irregular form of beating following an indifferent stimulus. This case suggests that, even when there has been an apparent cure of hyperthyroidism by subtotal thyroidectomy, an alteration of the metabolic processes of the heart muscle may persist, favoring a recurrence of auricular fibrillation.

## A CASE OF STREPTOCOCCIC MENINGITIS WITH RECOVERY

S. W. MARICK, M.D., PITTSBURGH

The subject of recovery from streptococcic meningitis was recently adequately reviewed by Gray.<sup>1</sup> He found sixty-five cases of recovery reported in the literature, to which he added his own case and made a plea for the report of other cases of streptococcic meningitis in which recovery occurred. I am therefore adding the following case:

### REPORT OF CASE

F. U., a woman, aged 28, entered the Montefiore Hospital, Oct. 22, 1935, for a hemorrhoidectomy, which was performed the following morning under spinal anesthesia.

The past history was unimportant, except that two days previously she had fallen and injured the lower part of the back and the buttocks. At the time of the operation the buttocks still looked bruised, but the lower part of the back appeared normal. She also had an old sinus on the neck following removal of tuberculous glands in childhood, which yielded a staphylococcus on microscopic examination.

Fever, excruciating headache, pain in the back of the neck and vomiting developed October 24. The patient continued to vomit until and including the morning of the 27th. Her vomiting was forceful but not typically projectile.

1. Gray, H. J.: Streptococcic Meningitis, *J. A. M. A.* 105: 92-96 (July 13) 1935.

I saw the patient October 27, at which time she complained of intense headache, pain in the back of the neck and vomiting.

Physical examination revealed rigidity of the neck, contracted pupils that did not react to light and in accommodation, irregular respirations, absence of abdominal reflexes, and a positive Kernig sign on the right.

The hyperesthesia of the lower extremities was so marked that they could barely be touched without the patient squirming. There was also some cyanosis of the fingertips.

A diagnosis of meningitis was made and a lumbar puncture ordered. The fluid from the spinal tap was cloudy, came out under pressure and contained 1,300 cells per cubic centimeter. The differential count showed 95 per cent polymorphonuclear leukocytes. A blood culture done the next day remained sterile.

The temperature rose to 103 F., ranged up to 104 for six days and then started to decline to normal, which level was maintained after six more days.

October 28 the patient complained of photophobia and the next day of double vision. I had started to tap the spinal canal every eight hours, removing only fluid under active pressure, while forcing dextrose solution by mouth, by enteroclysis and by hypodermoclysis. I did not inject the fluids intravenously because I preferred a slower absorption with a slower elimination.

October 29, with the temperature decreasing to 101 F., there was an abatement of all symptoms and the spinal fluid was getting clearer.

October 30 the spinal fluid appeared clear. The patient was subjectively free from complaint except as to vision and could move her neck freely from side to side. There was, however, considerable pain on pressure along the course of the nerves of the lower extremities.

October 31 the headache and rigidity of the neck recurred and the spinal fluid was again turbid. The following day the patient looked very toxic.

November 3 the temperature dropped to normal and after three days more remained at normal. With the drop in fever, the neck rigidity again became less and by the next day all symptoms were gone except for a doubtful Kernig sign on the right side. The spinal fluid was getting clear again.

November 4 the patient slept at long intervals and the spinal fluid was almost clear.

Facial neuralgia developed on the left side November 7, while there was twitching of the muscles of the right side of the face. By the 9th the patient had double vision only when looking to her left, and on the following day it was present only occasionally when her eyes felt tired. At this time she had quite a washed-out appearance.

A laboratory report of the spinal fluid disclosed a nonhemolytic streptococcus which grew poorly on subcultures and hence was of low virulence. Three cultures were done on different days and the same organism was recovered.

The fluid at the first tap was cloudy, then cleared up with an accompanying drop in fever and amelioration of all symptoms, only to become cloudy again with the return of all symptoms. The spinal fluid became clear a second time, when her temperature again dropped to normal, but was not absolutely clear with the last tap. Fibrin was present in the withdrawn fluid on several occasions. The amount withdrawn varied from 20 to 40 cc. The cell count varied from 1,300 to 450 on November 5, when the patient was free from symptoms.

The blood count showed a leukocytosis highest on October 27, when it was 23,400, with 92 per cent neutrophils.

Treatment consisted of spinal drainage every eight hours for the first four days, then twice daily until November 5, on which day only one tap was performed.

As already mentioned, 5 per cent dextrose in saline solution was injected subcutaneously and fluids were forced by mouth, and enteroclysis was also resorted to early in the treatment. On the average, the patient received close to 4 quarts (liters) of fluids daily. Milk, fruit juices, albumin, ice cream and thin gruels were given from the beginning, and as the patient's tongue was usually clean she was at times encouraged to take cooked vegetables. For the pain she received codeine hypodermically, one-half grain (0.03 Gm.) as her condition required, and occasionally whisky.

## COMMENT

The interesting features of this case, aside from the recovery of the patient, were that it followed spinal anesthesia through recently traumatized tissue, and the symptoms in the course of the disease temporarily disappeared together with the clearing up of the spinal fluid, only to return later. It would be interesting to discover whether a remission in the course of meningitis is always accompanied by a clearing up of the spinal fluid.

When the symptoms first disappeared I was inclined to give the spinal drainage credit for the result, but when they recurred it left me in doubt. Yet the repeated drainage may have cleared up first one infected area and then another. I merely drained off enough fluid at certain intervals to keep the spinal pressure down while forcing fluids. No special claims are made for this method of treatment. I used no serums, no intravenous medication and no blood transfusions.

It must also be borne in mind that the organism was of low virulence, which fact might have played a large part in the patient's recovery.

Retan<sup>2</sup> did not find spinal drainage useful in streptococcal meningitis. The method I employed was not, however, the same as Retan's.

The patient was last examined Jan. 11, 1936, and no residuals were found. She stated, however, that since the meningitis a previous tendency to headache and insomnia has become more marked.

**NEW AND NONOFFICIAL REMEDIES**

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

**DEXTROSE** (See New and Nonofficial Remedies, 1935, page 280).

The following dosage forms have been accepted:

*Dextrose 5% in Distilled Water in Filtrair Container:* Each 100 cc. contains dextrose, U. S. P., 5.50 Gm. Marketed in bottles containing 1,000 cc.

Prepared by Hospital Liquids, Inc., Chicago.

*Dextrose 10% in Distilled Water in Filtrair Container:* Each 100 cc. contains dextrose, U. S. P., 11.0 Gm. Marketed in bottles containing 1,000 cc.

Prepared by Hospital Liquids, Inc., Chicago.

*Dextrose 25% in Distilled Water in Filtrair Container:* Each 100 cc. contains dextrose, U. S. P., 27.5 Gm. Marketed in bottles containing 1,000 cc.

Prepared by Hospital Liquids, Inc., Chicago.

*Dextrose 5% in Physiologic Sodium Chloride Solution in Filtrair Container:* Each 100 cc. contains dextrose, U. S. P., 5.50 Gm. and sodium chloride, U. S. P., 0.85 Gm. Marketed in bottles containing 1,000 cc.

Prepared by Hospital Liquids, Inc., Chicago.

*Dextrose 10% in Physiologic Sodium Chloride Solution in Filtrair Container:* Each 100 cc. contains dextrose, U. S. P., 11.0 Gm. and sodium chloride, U. S. P., 0.85 Gm. Marketed in bottles containing 1,000 cc.

Prepared by Hospital Liquids, Inc., Chicago.

**METRAZOL** (See New and Nonofficial Remedies, 1935, p. 322).

The following dosage form has been accepted:

*Hypodermic Tablets Metrazol 1½ grains:* Each tablet contains metrazol sufficient to insure the administration of 1½ grains of metrazol in solution.

**SAL ETHYL CARBONATE** (See New and Nonofficial Remedies, 1935, p. 358).

The following dosage form has been accepted:

*Compressed Tablets Sal-Ethyl Carbonate with Phenacetin:* Each tablet contains sal-ethyl carbonate 0.23 Gm. (3½ grains) and phenacetin (acetophenetidin-U. S. P.) 0.1 Gm. (1½ grains).

**TETANUS TOXOID, ALUM PRECIPITATED** (See THE JOURNAL, May 16, 1936, p. 1735).

Lederle Laboratories, Inc., Pearl River, N. Y.

*Refined Alum Precipitated Tetanus Toxoid-Lederle.*—Marketed in packages of two 1 cc. vials (one complete immunization); and in packages of one 10 cc. vial (five complete immunizations).

## URINARY HISTIDINE IN THE DIAGNOSIS OF PREGNANCY

The early clinical diagnosis of pregnancy was greatly aided by the introduction of a laboratory test devised by Zondek and Aschheim in 1928. This test is based on an observation made in 1922 by Long and Evans, who demonstrated that intraperitoneal injections of fresh extract of the anterior lobe of the pituitary body caused an increase in weight of the ovaries of immature rats. Furthermore, large numbers of corpora lutea were formed in these ovaries. A short time later it was clearly established that the anterior pituitary exerted a powerful stimulant effect on the process of lutein cell formation.

Using these fundamental observations of Long and Evans and having demonstrated the presence of large amounts of gonadotropic substance in the urine of pregnant women, Zondek and Aschheim elaborated a technic for the diagnosis of pregnancy, basing their procedure on the detection of gonadotropic substance in the urine. The test involves the injection of portions of urine, over a period of forty-eight hours, into a group of infantile mice and a study of the ovaries of the injected animals at a definite time following the last injection. The ovaries are examined for ripening of follicles, for hemorrhagic points and for the formation of corpora lutea atretica. Utilizing this technic, Zondek and Aschheim found positive results in 98 per cent of the pregnancy cases tested. This test has yielded rather uniformly correct results in other laboratories and has been widely used in the clinical diagnosis of pregnancy. The Zondek-Aschheim test does have, however, the unfortunate feature of involving a considerable number of animals and of being relatively time consuming. Furthermore, the procedure is obviously best adapted to an adequate clinical laboratory and is of little aid to the practicing physician. In view of these difficulties, efforts have been made from time to time to develop a simple chemical test which might perhaps be carried out by the practitioner himself and which does not involve the use of animals.

One of the more promising of these devices appears to be the detection of urinary histidine, an amino acid which has been reported by Voge<sup>1</sup> to be absent from normal urine and present early in the urine of pregnancy. It is quite simple to conduct a chemical test for histidine, as this amino acid in solution gives, under definite conditions, a pink coloration on the addition of dilute bromine water. Voge has applied this test to a large number of urines and has compared the results obtained with those yielded by the application of the Zondek-Aschheim test to the same urines. The high degree of correlation between the results of the two methods has led to the suggestion that the bromine water test for histidine is of considerable aid in the diagnosis of pregnancy. This suggestion was supported by an actual isolation of histidine from pregnancy urine<sup>2</sup> and the demonstration that it was the presence of this amino acid in gravid urines that accounted for the positive bromine water reaction.

Several other investigators have been able to demonstrate a positive histidine test rather uniformly for pregnancy urine, and although the correlation with the Zondek-Aschheim test is not as good as that observed by Voge, the general uniformity of the results has indicated the value of a detailed study of the reaction. This has been initiated by Kapeller-Adler,<sup>3</sup> who, with collaborators, has had experience with the amino acid histidine. These Vienna investigators have applied a quantitative method, developed in their laboratory, to the determination of urinary histidine. It has been demonstrated that pregnancy urine may contain from 6 to 74 mg. per hundred cubic centimeters of this amino acid and that the compound is absent in the urine of normal men and women and in the various pathologic urines tested. In later investigations, these workers<sup>4</sup> have followed the excretion of histidine by a pregnant woman throughout the course of the pregnancy. The amino acid appeared in the urine at about the fifth week of gestation. The amount of urinary histidine was significantly greater on a meat diet, and orally administered histidine was eliminated unchanged. The excretion of this compound ceased on the third day post partum, and histidine given to the same individual several months later was completely metabolized. The authors present experiments which, they believe, support the hypothesis of an inhibition of the activity of liver histidinase in the liver of pregnant women; the failure of this enzyme to catalyze the catabolism of histidine would account for the presence of this amino acid in the urine.

These interesting results merit consideration, in view of the readiness with which the bromine water test can

1. Voge, C. I. B.: *Brit. M. J.* 2: 829 (Nov. 2) 1929; *Proc. Roy. Soc. Med.* 23: 638 (March) 1930.

be conducted. However, a recent investigator<sup>5</sup> has cautioned against enthusiastic interpretation of the results obtained by the application of the histidine test for pregnancy. With a slightly modified bromine test it has been confirmed that the test for histidine is seldom positive in nonpregnant women. However, although frequently positive in urines from pregnant women, the significant number of negative tests on such urines makes the value of the reaction as a pregnancy test somewhat questionable. There appears to be a relationship between the likelihood of a positive reaction for histidine and the specific gravity of the urine, the intensity of the test varying directly with the magnitude of the specific gravity values. This relationship may merely be a manifestation of a limit to the concentration of urinary histidine that can be detected by the test. Further data must be secured in order to determine definitely whether this relatively simple chemical test for urinary histidine may be of at least some value in the clinical diagnosis of pregnancy. The ease with which the test is conducted should encourage thorough investigations of its value and significance.

#### HEMOLYTIC SHOCK AFTER BLOOD TRANSFUSION

The problem of hemolytic shock is assuming a greater theoretical and practical significance because of the wider adaptation of blood transfusion. Interesting clinical and experimental observations are analyzed by E. P. Gesse<sup>1</sup> in a review of twenty-two papers emanating from the First Surgical Clinic and the Research Institute for Blood Transfusion in Leningrad (E. P. Gesse, chief). According to Gesse and his co-workers, hemolytic shock is a complex concept of manifestations on the part of the blood vessels and the heart, accompanied by a depression of the nervous system and caused by transfusion of incompatible blood. They were able to demonstrate in animal experiments that<sup>2</sup> depressor substances released from the broken down erythrocytes act directly on the blood vessel wall, causing arterial spasm, dilatation of the capillary bed, stasis and a sharp fall in the blood pressure. The cardiac action is secondarily affected as the result of insufficient flow of blood to the heart during the diastole. The manifestations are, as a rule, quickly compensated and are succeeded by a secondary phase provoked by the spasm of the renal arteries and the hemolysis. Derangement of the renal function ensues as the result of toxic action of the products of broken down red cells.

Gesse was able to collect 217 cases of hemolytic shock following blood transfusion. These were recorded in the literature and in replies to 1,700 questionnaires sent out to large hospitals and clinics. In his own series of

2,360 transfusions there were six instances of hemolytic shock (0.25 per cent). The mortality rate for the collected group amounted to 56 per cent. Hemolysis occurred occasionally after transfusion of compatible, conserved blood. It was due either to the hemolysis of the conserved blood, to its being overheated, or to the denatured albumins. The older the blood the greater was the danger of hemolysis.

Excruciating pain in the lumbar region is the most characteristic, in fact, the pathognomonic subjective symptom of hemolytic shock. It is caused by the spasm of the renal arteries, is ischemic in nature and cannot be controlled by morphine. The most important objective signs are the fall in the blood pressure and the increased intestinal peristalsis. Gesse suggests a classification of cases into an acute form with mild and with severe manifestations, and a delayed form. Hemolytic shock results, as a rule, from transfusion of a large amount of incompatible blood. Cases, however, were reported in which fatal shock followed the transfusion of small doses. In forty-six cases, shock developed after transfusion of blood from a universal donor. Possibility of hemolysis is to be kept in mind when amounts larger than 200 cc. of blood from a universal donor are to be used, when the recipient exhibits a severe anemia, and in the presence of a high serum titer of the donor with regard to the recipient's erythrocytes.

A satisfactory method of dealing with the hemolytic shock of blood transfusion did not exist prior to 1932. Intravenous administration of dextrose exerted in some cases a powerful diuretic effect. Decapsulation of the kidneys did not prove successful. In 1932 Filatov and Gesse<sup>3</sup> suggested the method of secondary transfusion with compatible blood as the method of treatment of hemolytic shock. The authors transfused dogs with fatal doses of hemolyzed blood, causing a maximal fall in the blood pressure and cessation of respiration. Transfusion with compatible homogeneous blood revived the animals. The method was applied in human beings in sixteen instances with fourteen recoveries. The secondary transfusion should be performed at the earliest possible moment after the development of hemolytic shock. The method, however, was successful in four cases in which secondary transfusion with compatible blood was undertaken from twenty-four to forty-eight hours after the onset of the symptoms. Amounts of from 200 to 300 cc. of compatible blood are sufficient for the purpose of detoxication, although the arterial spasm is relaxed after the infusion of from 25 to 30 cc., as evidenced by the prompt cessation of the excruciating lumbar pain. Large amounts are contraindicated in the presence of a renal lesion. When hemoglobinuria and anuria are present, the intravenous administration of dextrose is indicated.

### SEPTICEMIA DUE TO ANAEROBIC ORGANISMS

In 1935 Pham-Huu-Chi,<sup>1</sup> according to Lemierre,<sup>2</sup> published a heavily documented monograph on certain septicemias due to anaerobic organisms. This work, being a special thesis, is difficult to obtain; fortunately a brief summary now exists in English in an address by Lemierre.<sup>2</sup> Several species of anaerobic organisms, specifically distinct from one another but possessing the common character of living as saprophytes in the natural cavities of the human body, can cause these special septicemias. All these organisms are fragile, are slightly motile, and grow only sparsely on culture mediums. To this group of organisms belong those gram-negative and non-spore bearing bacilli which certain bacteriologists group together under the name of *Bacteroides*. With them must also be placed several gram-positive anaerobic streptococci and staphylococci, which have been variously named.

A septicemia with these organisms arises from inflammatory or suppurative lesions in the tissues or cavities where the organisms normally exist under physiologic conditions. The most common locations for these inflammatory lesions are the nasopharynx, particularly tonsillar and peritonsillar abscesses, similar regions of the mouth and jaws, the urinary passages and the structures involved in otitis media or mastoiditis, purulent endometritis following parturition, and appendicitis. Whatever the origin, according to Lemierre, the inflammatory lesions present certain common clinical aspects that enable them to be grouped together. The postanginal septicemias due to anaerobic organisms most frequently seen in Paris are due particularly to *Bacillus funduliformis*, which can usually be isolated in pure culture from the blood and from secondary abscesses. The bacillus is sometimes associated with an anaerobic streptococcus.

Clinically the disease usually affects young adults or adolescents, and the two sexes about equally. It has been believed since 1919 that these septicemias are the result of a thrombophlebitis of the tonsillar and peritonsillar veins, which can spread to the internal jugular vein or even to the facial vein. Lemierre agrees with this opinion. The first symptom is a notable rise of temperature to 103 F., often with rigors. There is usually painful swelling of the glands below the maxillary angle, generally unilateral. Most of the septicemias are accompanied by the formation of distant metastatic abscesses. The abscesses are commonly located in the lungs and may occur quite early. They are septic infarcts, leading almost invariably to multiple abscess formation with intense thoracic pain, dyspnea, sometimes blood-stained sputum, pleural frictions, and localized areas of subcrepitant râles. Articulation

lesions are frequent. Icterus has often been noted. Renal lesions, thyroid lesions and metastatic lesions almost everywhere have sometimes occurred. Fatal progress may occur rapidly. The final diagnosis is established by bacteriologic examination. *Bacillus funduliformis* is easy to discover in the purulent effusions, but blood culture on anaerobic mediums gives the earliest definite information. Positive results are particularly easy if the blood is taken during a chill. The treatment has been discussed elsewhere by Lemierre and Pham.<sup>3</sup> Intravenous injection of acridine yellow and blood transfusions have not seemed to influence the course. Furthermore, great hopes cannot be founded on specific serotherapy, since attempts to immunize animals have resulted in poor antibody production. At present the medical treatment must remain purely symptomatic.

There is a definite similarity between the anaerobic septicemias arising from the other organs of the body. Frequently *Bacillus funduliformis* is also a saprophyte in the pelvic organs, the appendix or the ear. Hence localized inflammations in these organs may also result in anaerobic septicemia. Septicemias with other anaerobic organisms, such as *B. fragilis*, *B. radiiformis*, *B. ramosus*, *B. fusiformis* and *B. symbiophiles*, have also been described. The apparent rarity of the disease in this country may cease with a more frequent recognition of the possibility of septicemias being due to organisms of this group.

### Current Comment

#### PRESSURE IN COMMON DUCT AND RELIEF OF PAIN FOLLOWING CHOLECYSTECTOMY

Elsewhere in this issue<sup>1</sup> are probably the first two reports published of direct observations and measurements of pressure in the common bile duct of man. The observations reported by Kipp were made on a man with a benign stricture of the common duct at the ampulla of Vater on whom he had performed a cholecystogastrostomy. Kipp also demonstrated clinically that certain extrinsic factors influenced the flow of bile in this patient. McGowan, Butsch and Walters made their observations on patients on whom a cholecystectomy had been performed. Many years ago Judd and Mann<sup>2</sup> demonstrated experimentally the dilatation of the common bile duct that follows removal of the gallbladder. Nearly ten years later Potter and Mann<sup>3</sup> measured in the laboratory the increase in intraductal pressure following removal of the gallbladder. Now, McGowan, Butsch and Walters,<sup>1</sup> with the cooperation

of patients, have not only shown that what is true of intraductal pressure of animals also is true of intraductal pressure of man but they have demonstrated that morphine, the therapeutic standby for postcholecystectomy colic, actually makes worse the condition that causes the pain. Of course, the pain disappears following administration of morphine just as it would if a black-jack had been employed; the sensory part of the brain ceases to function but the intraductal pressure rises. With the administration of a nitrite, pressure within the common bile duct drops and pain ceases. Now, therefore, the results of the long research become applicable in the everyday work of the physician. This applicability in itself is sufficiently important. However, it illustrates again the interdependence of the sciences and of the medical specialties. Surgeons, in these reports from the bedside, have contributed to drug therapy and pointed out new paths of investigation for the pharmacologists, one of which is to determine whether biliary colic after administration of morphine is attributable to malfunction of the sphincter of Oddi or to closure of the intraduodenal portion of the common bile duct consequent on increased duodenal peristalsis.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ARIZONA

**Personal.**—Dr. Willis D. Gilmore, Tombstone, has been appointed tuberculosis consultant for the Arizona State Board of Health.—Dr. Jack B. Eason, Tucson, health officer of Pima County, has been placed in charge of the new health unit in Yuma County.

### CALIFORNIA

**Society News.**—Dr. Clifford V. Mason, Livermore, among others, addressed the Alameda County Medical Association in Oakland, June 15, on "Pneumoperitoneum in the Treatment of Pulmonary Tuberculosis."—Dr. Frederick Proescher, San Jose, addressed the Los Angeles Society of Neurology and Psychiatry, June 17, on "The Nature of the Neurotropic Viruses, Rabies and Poliomyelitis."—At a meeting of the Hollywood Academy of Medicine, May 21, Aberdeen O. Bowden, Ph.D., Los Angeles, discussed "Early Medicine and Its Relation to Magic and Religion."

**Tuberculosis Death Rate Lowered.**—There were 4,516 deaths from tuberculosis registered in California in 1935 as compared with 4,611 deaths in 1934, giving rates of 72 and 74.9, respectively, per hundred thousand of population. Of the 4,516 persons, 3,179 had lived within the state for ten years or more, 576 had lived in California from five to nine years, 357 from one to four years, and 186 had lived in the state for less than one year. Of this group, 4,105 deaths were attributed to tuberculosis of the lungs, 131 to tuberculosis of the meninges and 103 to disseminated tuberculosis.

### CONNECTICUT

**Anniversary of Health Bulletin.**—The *Connecticut Health Bulletin* celebrated its fiftieth anniversary with the May issue. The bulletin reproduces various covers and pages from its earlier issues. The first number of the bulletin appeared in June 1887 and it has been printed continuously since that time.

**Expansion of Health Department.**—Federal funds granted under the Social Security Act have made possible two new positions in the Connecticut State Health Department, it is reported. Franklin M. Erlenbach, Boston, will fill the newly created position of chief of the division of mouth hygiene in the bureau of child hygiene, and Mrs. Helen S. Peterson, New

York, the new position of assistant mental hygienist in the bureau of mental hygiene. Under the new arrangement Miss Anna Katherine Tobias, formerly of West Hartford, has been named librarian of the department. Dr. Henry P. Talbot, who has been studying for the past year at the Harvard School of Public Health, was to return June 1 as director of the bureau of venereal diseases; he was on leave of absence. Dr. Alfred L. Burgdorf, acting director of the bureau, will be transferred to the bureau of preventable diseases.

### FLORIDA

**New Health Units.**—The Gadsden County Health Department was recently organized with headquarters in Quincy. Dr. Charles W. McDonald, formerly director of county health work, Alabama State Department of Health, it is reported, is in charge of the new unit. Dr. Herbert A. McClure is health officer of the newly created health department in Taylor County, with headquarters in Perry.

### ILLINOIS

**Outbreak of Smallpox.**—According to the state department of health, seventeen new cases of smallpox were reported in Will County during the week ended June 1. Three cases were reported in Whiteside County. The twenty new cases during this week compare with four for the corresponding week last year, while 251 cases have been reported for this year against thirty-six for the similar period of 1935.

**Society News.**—Dr. Winston H. Tucker, Springfield, addressed the thirty-seventh annual meeting of the Sangamon County Medical Society in Springfield, June 4, on "Diagnosis and Treatment of Poliomyelitis."—Dr. George D. Hauberg, Moline, was chosen president of the Iowa-Illinois Medical Association at its annual meeting in Davenport, May 26.—Dr. Richard H. Jaffé, Chicago, discussed "Precancerous Lesions" before the Peoria City Medical Society, June 16.

### Chicago

**Personal.**—Dr. Walter W. Hamburger, whose resignation as assistant clinical professor of medicine at Rush Medical College was recently announced, will remain at the Department of Medicine, University of Chicago, as clinical professor of medicine.

**Dr. Meek Gives Luckhardt Lecture.**—Walter J. Meek, Ph.D., department of physiology, University of Wisconsin School of Medicine, Madison, delivered the third annual lecture under the Arno B. Luckhardt Lectureship at the University of Chicago, May 21. His lecture was entitled "A Present Day Concept of Shock." The lectureship was established in the medical school by the Delta chapter of Phi Beta Pi.

**Amateur Night and Annual Banquet.**—The annual banquet of the Chicago Medical Society with the installation of officers took place June 17. Dr. Julius H. Hess, retiring president, made a brief address and installed Dr. Thomas P. Foley as president. The president-elect is Dr. George W. Post. On behalf of the society Dr. Charles H. Phifer presented Dr. Hess with a fine camera. The entertainment included an amateur night at which all the performers were either physicians or members of the families of physicians.

**Rush Medical College of the University of Chicago.**—At the annual faculty alumni dinner at Rush Medical College, June 16, announcement was made by Vice President Fred-eric Woodward for the university that the School of Medicine of the Division of Biological Sciences at the University of Chicago and Rush Medical College are now combined in one institution to be known as the Rush Medical College of the University of Chicago. Undergraduate medical education will be continued at the west side school. The medical schools are united in one departmental organization under the dean of the biological sciences. On the west side Dr. Emmet B. Bay will be associate dean. It is proposed within the next five years to diminish the number of medical students greatly and to introduce graduate instruction on an increasing scale into the curriculum with the possibility that eventually graduate study will supersede undergraduate study entirely on the west side. An ovation was tendered to Dr. Ernest E. Irons, who retires as dean to assume the title of professor of medicine. He will remain as chairman of the department of medicine. In his address Dr. Irons pointed out that 1937 will mark the centennial of the charter of Rush Medical College and it is proposed to celebrate the occasion fittingly at the time of the 1937 convocation. A committee was appointed to draw up plans for the celebration of the centennial with Dr. Robert H. Herbst as chairman.

## INDIANA

**University News.**—An anonymous donor has given a collection of medical memorabilia to the museum of Indiana University School of Medicine, Indianapolis. The collection includes a volume of original notes made by Dr. Robert Cravens of Madison when attending lectures given, among others, by Dr. Caspar Wistar, who published the first American "System of Anatomy"; on materia medica by Dr. Nathaniel Chapman; on surgery by Dr. Physick and Dr. Dorsey, and on midwifery and the diseases of women and children by Dr. Thomas Chalfley James. Original signatures of the lecturers are included in the collection. Dr. Cravens died in 1821.

**District Meetings.**—At a meeting of the Eleventh Indiana Councilor District Medical Association in Marion, May 20, Drs. Andrew L. Banyai, Wauwatosa, Wis., spoke on "Childhood Tuberculosis"; Lall G. Montgomery, Muncie, "Primitive Tubercle"; Arthur B. Richter, Flora, "Treatment of Nephritis," and James Charbonnier, B.D., Upland, head of the department of theology and classical languages of Taylor University, "Present European Situation."—The Ninth Councilor District Medical Society was addressed in Lafayette, May 19, by Drs. Frederick A. Collier, Ann Arbor, "The Acute Abdomen"; Jerome R. Head, Chicago, "Treatment of Acute and Chronic Empyema"; William H. Park, New York, "Management and Control of the Communicable Diseases," and Robert J. Masters, Indianapolis, "The Ophthalmoscope as a Help in Diagnosis of Disease."—At a meeting of the Union District Medical Association in Newcastle, May 28, Mr. Albert Stump, Indianapolis, discussed "The Doctor and the Law"; Drs. Max M. Zinninger, Cincinnati, "Treatment of Acute Head Injuries"; Larue D. Carter, Indianapolis, "The Neuroses"; Charles J. McIntyre, Indianapolis, "Observation in Tuberculosis," and George Wiggins, Newcastle, "Industrial Dermatitis."—The Sixth District Medical Society was addressed in Shelbyville, May 21, by Drs. Joseph L. Allen, Greenfield, who gave the address of welcome; Johnson McGuire, Cincinnati, "Cardiac Irregularities and Treatment"; Louis H. Segar, Indianapolis, pediatrics; Homer H. Wheeler, Indianapolis, "Rectal Diseases Most Frequently Encountered in Practice"; Howard B. Mettel, Indianapolis, "Relation of Indiana Bureau of Maternal and Child Health to Local Medical Society," and Bayard G. Keeney, Shelbyville, cancer.

## LOUISIANA

**Personal.**—Dr. Hilliard E. Miller, assistant professor of gynecology, Tulane University of Louisiana School of Medicine, New Orleans, has been appointed chief of the department of gynecology at Toussaint Infirmary, succeeding his brother, the late Dr. Charles Jefferson Miller.

**Society News.**—At a meeting of the Orleans Parish Medical Society in New Orleans, May 25, speakers were Drs. James Ross Veal and Benjamin D. D. Van Werden on "Post-operative Pulmonary Complications"; Manuel Gardberg, "Diabetic Infection and Gangrene," and Henry Theodore Simon, "Role of the Semilunar Cartilage in the Football Knee." At a special meeting of the society, April 20, Drs. Horton R. Casparis, Nashville, Tenn., discussed "Child Tuberculosis"; Max Pinner, Oneonta, N. Y., "Diagnostic and Prognostic Significance of Negative Sputum"; Paul P. McCain, Sanatorium, N. C., "Epidemiologic Aspects of Tuberculosis," and Lewis J. Moorman, Oklahoma City, "Compression Therapy."

## MAINE

**Society News.**—At a meeting of the Kennebec County Medical Association in Togus recently the speakers included Drs. Hanson T. Perkins, on "Diagnosis of Myocarditis"; James H. Pennington, "Report of a Series of Cases of Chronic Appendicitis"; Joseph E. Wheeler, "Amputations," and Harry Levine, "Nephritides."

## MICHIGAN

**Personal.**—Dr. George P. Myers, Detroit, has been appointed chief surgeon of the Michigan Central Railroad and acting medical director of the New York Central system, succeeding the late Dr. William L. Hartman.

**County Societies and Medical Economics.**—To aid in the adoption of a statewide program of medical economics the chairman of the medical economics committee of the state medical society has sent a letter to the officers of every county medical society urging a survey of this subject in their territory. The committee desires to know what the societies have done during the past twelve months and what they hope to accomplish in the next year.

**Society News.**—Dr. Frederick G. Buesser, Detroit, discussed "Medical Treatment of Peptic Ulcer" before the Lapeer County Medical Society recently.—The St. Clair County Medical Society was addressed, May 19, on "Practical Value of Intravenous Urography."—Dr. Alfred H. Whittaker, Detroit, was elected president of the Michigan Industrial Physicians and Surgeons' Association at its annual meeting in Jackson, May 8; Dr. Donald F. Kudner was reelected secretary and Detroit was selected as the place for the 1937 meeting.

## MINNESOTA

**Society News.**—Dr. John Richards Aurelius, St. Paul, was chosen president of the Minnesota Radiological Society at its recent annual meeting; Dr. Walter H. Ude, Minneapolis, vice president, and Dr. Leo G. Rigler, Minneapolis, secretary. Dr. Willis F. Manges, Philadelphia, discussed "The Future of Radiology" at the annual dinner.—Dr. Thomas B. Cooley, Detroit, addressed the Northwestern Pediatric Society in St. Paul, May 7, on "Constitutional Hemolytic Anemias."—At the annual dinner of the Red River Valley Society in Crookston recently Dr. William T. Peyton, Minneapolis, spoke on "Tumor of the Breast."

**Personal.**—Dr. James R. Kingston, Deer River, has been appointed director of public health for the northern Minnesota district, with headquarters in Grand Rapids; he will share his practice in Deer River with another physician.—Dr. Arrah B. Everts, senior assistant physician, Rochester State Hospital, resigned June 1. She was presented with a gift of silver, May 15, by the employees of the hospital, with which she had been associated since 1918.—Dr. Charles E. Lyght, assistant professor of medicine and acting chief of student health, University of Wisconsin Medical School, Madison, has been appointed professor of health and director of physical education for men at Carleton College, Northfield.

## MISSOURI

**Society News.**—Dr. Thomas G. Orr, Kansas City, addressed the Buchanan County Medical Society in St. Joseph, June 3, on "Treatment of Disease of the Gall Tract."—Dr. Arthur E. Hertzler, Halstead, Kan., addressed the St. Louis County Medical Society, June 24, on "Effects of Total Thyroidectomy with Differentiation Between the Degenerative Toxicity and the Hyperplastic Toxicity"; the St. Louis Medical Society was invited.—Dr. Edmund Henry M. Lissack, Concordia, read a paper on "Breach Presentation" before the Johnson County Medical Society, May 13.

## NEW YORK

**Syracuse Alumni Meeting.**—The Medical Alumni Association of Syracuse University School of Medicine held its annual meeting June 1-2. Demonstrations were presented at the University Hospital of the Good Shepherd, St. Joseph's and Syracuse Memorial hospitals. Dr. Anton J. Carlson, professor and chairman of the department of physiology, University of Chicago, was a guest speaker at a luncheon meeting and at a banquet in the evening.

**Society News.**—Dr. Harold E. Himwich, Albany, addressed the Medical Society of the County of Albany, May 27, on "Blood Sugar in Diabetes."—The Medical Society of the County of Saratoga held its annual spa therapy meeting at Saratoga Springs June 4. Speakers were Drs. Richard Kovacs, New York, on "Newer Methods of Heat Therapy"; Lee A. Hadley, Syracuse, "Diagnosis and Physical Therapy Treatment of Certain Painful Conditions of the Back"; Ralph Pemberton, Philadelphia, and Robert B. Osgood, Boston, medical and surgical aspects, respectively, of arthritis.—Dr. George W. Crile, Cleveland, addressed the Utica Academy of Medicine, May 14, on "Genesis and Treatment of Essential Hypertension."—Dr. Edward D. Churchill, Boston, addressed the Glens Falls Academy of Medicine, May 14, on "Lobectomy, Pneumonectomy and Thoracoplasty."

## New York City

**Personal.**—Dr. Thomas Hodge McGavack, formerly of the University of California Medical School, San Francisco, has been appointed associate professor of medicine, beginning July 1, at the New York Medical College and Flower Hospital.

**Society News.**—Health officers of the metropolitan area, including parts of New Jersey and Connecticut, formed the Metropolitan Health Officers' Conference at a meeting, June 5, at the New York City Department of Health building. Dr. Matthias Nicoll Jr., health commissioner of Westchester

County, was made temporary chairman and Dr. Charles F. Bolduan, of the New York health department, temporary executive secretary.

**Hospital News.**—Dr. Max Seide has been appointed superintendent of Cumberland Hospital, Brooklyn, to succeed Dr. Marcus D. Kogel. —Dr. Jack Masur has been appointed assistant director of Montefiore Hospital to succeed Dr. Morris Hinenburg, now medical director of the Brooklyn Jewish Hospital. —Dr. Carlos Monge of the Faculty of Medicine, Lima, Peru, and a member of the International High Altitude Expedition, discussed "Studies in High Altitudes: Chronic Mountain Sickness" at Mount Sinai Hospital, May 1.

**Dr. Park to Retire from New York University.** —Dr. William H. Park, Biggs professor of preventive medicine and director of bacteriological laboratories, New York University College of Medicine, has been granted a leave of absence for the session of 1936-1937 and will retire after that period. Dr. Park, who is now 72 years old, has been connected with the university since 1895. He was professor of bacteriology and hygiene from 1900 to 1933, when he received his present title. In the session of 1914-1915 he was dean of the school. Dr. Park, for many years director of the department of laboratories of the New York City Department of Health, reached the retirement age for that position Dec. 20, 1933, but his term of service was extended and was again extended, June 5, to September 30.

### OKLAHOMA

**Society News.**—Drs. Everett S. Lain and Minard F. Jacobs, Oklahoma City, conducted a cancer clinic as guests of the Woods-Alfalfa Counties Medical Society in Cherokee, May 26. —Dr. Raymond G. Jacobs, Enid, addressed the Garfield County Medical Society, April 30, on "Fractures of the Long Bones."

**Personal.**—Joseph B. Goldsmith, Ph.D., has been promoted to be associate professor of histology and embryology at the University of Oklahoma School of Medicine, Oklahoma City. —Dr. Joseph B. Carmichael, Duncan, has been appointed health officer of Stephens County to succeed the late Dr. Dock Long, Duncan.

### PENNSYLVANIA

**Society News.**—The fourth monthly graduate assembly of the Montour County Medical Society at Danville, June 5, consisted of a symposium on diseases of the eye, ear, nose and throat by Drs. George H. Cross, Chester; Frank C. Hammond, Philadelphia; John R. Simpson, Pittsburgh, and Francis W. Davison, Danville. Dr. Alexander H. Colwell, Pittsburgh, president, Medical Society of the State of Pennsylvania, gave an address and Dr. Harold L. Foss conducted an operative clinic. —The spring meeting of the central Pennsylvania branch of the Society of American Bacteriologists was held at Geisinger Memorial Hospital, Danville, May 16. Among speakers were Drs. Francis W. Davison, on "Clinical Manifestations of Bacterial Sensitivity" and John F. Conway, "Value of Pre-medical Training in Bacteriology." —Drs. Eben W. Fiske and Harold W. Jacox, Pittsburgh, conducted a seminar on physical therapy at Waynesburg, June 9, for the Greene County Medical Society under the auspices of the committee on physical therapy of the Medical Society of the State of Pennsylvania. —Dr. Ralph Pemberton, Philadelphia, addressed the Lehigh County Medical Society, Allentown, in April, on the treatment of arthritis. —Dr. I. Newton Kugelmass, New York, addressed the York County Medical Society, June 20, on "Blood Dyscrasias in Infancy and Childhood."

#### Philadelphia

**Society News.**—Dr. William D. Stroud was recently elected president of the Philadelphia Heart Association. —Dr. Albert E. Bothe addressed the Philadelphia Urological Society, May 25, on "Benign Hypertrophy of the Prostate with Tuberculosis." Dr. Bothe was elected president.

**Personal.**—Dr. Louis Tuft has been appointed to succeed Dr. John L. Laird as head of the laboratory in the state department of health. —Dr. P. Brooke Bland received the honorary degree of doctor of science at the commencement exercises of Franklin and Marshall College, Lancaster, June 3.

**Jefferson Alumni Dinner.**—The annual dinner of the Alumni Association of Jefferson Medical College was held at the Bellevue-Stratford Hotel, June 4, with more than 500 alumni present. Dr. Charles E. G. Shannon, president of the association, presided and speakers were Mr. Van Horn Ely, a trustee of the college; Dr. David M. Davis, professor of genito-urinary surgery; Dr. James W. Tankersley, Greensboro, N. C., representing the class of 1906; Dr. Andrew Wallhauser,

Pittsburgh, the class of 1916; Dr. Neal R. Moore, Bay City, Mich., the class of 1926, and Dr. Leonard W. Parkhurst, Wilkes-Barre, the class of 1936.

### RHODE ISLAND

**Personal.**—Dr. Henry Antonio Rosa has been named medical examiner in Portsmouth. Dr. Ralph J. Petrucci has been appointed medical examiner for the towns of Barrington and Warren. —Dr. Seth F. H. Howes, assistant superintendent of the State Infirmary, Howard, has been appointed superintendent to succeed Dr. Karl B. Sturgis.

### TENNESSEE

**Society News.**—Dr. Raymond Wallace addressed the Hamilton County Medical Society, Chattanooga, June 4, on "Recent Trends in Gynecologic Surgery." —Drs. George J. Sells and Raymond D. Tompkins, Johnson City, addressed the Washington County Medical Society, May 7, on angioneurotic edema and pain in the heart, respectively. —Dr. Jarrell Penn, Knoxville, discussed acute injuries to the back, May 5, at the meeting of the Knox County Medical Society, Knoxville. —Dr. George A. Hendon, Louisville, Ky., addressed the Nashville Academy of Medicine, May 26, on "Treatment of Fractures, with Special Reference to Ununited Fractures." —Drs. Robert L. Sanders and Thomas C. Moss addressed the Memphis and Shelby County Medical Society, May 5, on "Clinical Observations in 100 Cases of Cyclopropane Anesthesia" and "Aberrant Endometrium" respectively. Speakers at a meeting May 18 were Drs. David H. James and Joseph H. Francis on "Megacolon" and "Sympathetic Ophthalmia" respectively.

### VIRGINIA

**Personal.**—Dr. Charles Howe Eller, Charlottesville, has resigned as health officer of Albemarle County to become assistant director of rural health with the state health department, it is reported, and Dr. Adrian L. Carson, health officer of Fairfax County, has been made director of the bureau of maternal and child hygiene. Dr. Edward M. Holmes Jr., Richmond, has been appointed health officer for Fairfax County to succeed Dr. Carson.

**Society News.**—Speakers who addressed the Southside Virginia Medical Association at its quarterly meeting in South Hill, June 9, were the following Richmond physicians: Drs. Arthur S. Brinkley, on "An Unusual Case of Intestinal Obstruction"; William Lowndes Peple, "Radium in the Treatment of Nonmalignant Uterine Conditions"; Douglas G. Chapman, "Mechanism and Electrocardiographic Registration of Heart Beat in Health and Disease"; Paul D. Camp, "Clinical Diagnosis of Irregularities of the Heart," and William R. Jordan, "Care of the Feet in Diabetes."

### WISCONSIN

**Society News.**—Drs. Paul F. Doege, Marshfield, and Edwin G. Bannick, Rochester, Minn., addressed the annual meeting of the Ninth Council District of the State Medical Society of Wisconsin, May 7, at Stevens Point, on "Determination of Degrees of Malignancy as Applied to the Uterine Cervix" and "Treatment of Nephritis" respectively. —Drs. Arlie R. Barnes and Harry M. Weber, Rochester, Minn., addressed the April meeting of the Eau Claire-Dunn-Pepin County Medical Society on "Pulmonary Embolism: Its Effect on the Heart and Its Clinical Recognition" and "Roentgenologic Manifestations of the More Commonly Encountered Lesions of the Large Intestine" respectively. —Dr. Frank J. Hirschboeck, Duluth, Minn., addressed the Douglas County Medical Society, May 13, on "The Nervous Patient." —Dr. Edward K. Steinkopf, Pewaukee, addressed the Washington-Ozaukee County Medical Society, May 7, on modern treatment of tuberculosis. —Speakers at a meeting of the Milwaukee Society of Clinical Surgery, May 6, were Drs. Leland S. McKittrick, Boston, on "Management of Deep Infections of the Hand in Patients with Diabetes Mellitus"; Harry P. Ritchie, St. Paul, "Congenital Clefts of the Face and Jaws—Problems of Repair" and William J. Carson, Milwaukee, "Tuberculous Appendicitis." —Dr. Cyril G. Richards, Kenosha, was elected president; Dr. Harry E. Kasten, Beloit, vice president, and Dr. Sidney J. Silbar, Milwaukee, secretary, of the Wisconsin Urological Society at the annual meeting in Marshfield, April 23.

### PUERTO RICO

**University News.**—Dr. James W. Jobling of the department of pathology, Columbia University College of Physicians and Surgeons, represented the university at the annual meeting of the board of trustees of the School of Tropical Medicine at the University of Puerto Rico, which is conducted under

the auspices of Columbia. Dr. Chung-Un Lee, Peiping Union Medical College, Peiping, China, is spending some time at the school carrying out investigations of diseases caused by parasites.

### GENERAL

**Council on Birth Control.**—The National Medical Council on Birth Control has recently been formed to control and supervise medical policies of the American Birth Control League and to initiate, encourage and execute appropriate scientific research in the medical aspects of birth control. Dr. Frederick C. Holden, New York, is chairman and Dr. Eric M. Matsner, New York, executive secretary of the executive committee. Other members are Drs. Eliot Bishop, Brooklyn; Foster Kennedy, Edgar Mayer, Richard N. Pierson and Wilbur Ward, New York; Abraham N. Creadick, New Haven; Owen J. Toland, Philadelphia, and Prentiss Willson, Washington, D. C.

**French Information Center.**—The formation of the "French Information Center," with headquarters in New York and Paris, is announced. Representatives of various French and American activities have formed an association, by which the project will be financed. Membership is open to both French and American institutions, corporations and individuals. The New York office plans to keep on file reference books, statistics, periodicals and newspapers covering a wide range of questions and will attempt to gather documents not to be found in America at present or not easily accessible. The New York office announces that it has received a quantity of documentary material pertaining to French medicine and will be glad to place this material at the disposal of American physicians and aid them in any problem they may have concerning medicine in France.

**Changes in Status of Licensure.**—The state board of medical education and licensure of Pennsylvania recently reported the following action:

License of Dr. Richard P. Jahnig, whose last known address was Pottstown, Pa., suspended indefinitely, April 16, because of violation of the narcotic laws.

The New Jersey board of medical examiners reported the following action:

License of Dr. James M. Hackett, Leonia, N. J., revoked March 18, for conviction of the crime of criminal abortion.

The California State Board reported the following actions taken at the meeting, March 9-12:

Dr. Woodward B. Mayo, Los Angeles, license revoked for violation of probation.

Dr. Walter F. Pike, Oakland, placed on probation for five years without narcotic privileges.

Dr. William N. Powers, Los Angeles, license revoked for conviction of a felony.

Dr. Robert Bremner Smith, Yountville, license revoked for federal narcotic conviction.

Dr. Carl W. Wahrer, Seymour, Iowa, formerly of Sacramento, license revoked for federal narcotic conviction.

**Bequests and Donations.**—The following bequests and donations to medical institutions have recently been announced:

Lincoln Hospital, New York, \$1,000 by the will of the late Henry Wollman.

Paterson (N. J.) General Hospital, \$15,000 and its junior auxiliary, \$5,000 by the will of Mrs. Louise J. E. Whitehead.

United Hospital Fund, the residuary estate of the late Reid A. Kathan, estimated in 1929 at \$727,660, under the recently filed will of his widow.

Mount Sinai Hospital, \$25,000; New York Eye and Ear Infirmary, Lenox Hill and Montefiore hospitals, \$20,000 each; Beth Israel Hospital, \$15,000, and New York Polyclinic Hospital, \$10,000 by the will of Mrs. Madeleine S. Stern. All the hospitals are in New York.

University of Cincinnati College of Medicine, \$5,000 from Mrs. Christian R. Holmes for research in internal medicine and \$4,000 from Miss Mary Hanna to purchase 100 mg. of radium for the department of surgery.

Episcopal Hospital, Philadelphia, \$30,000 by the will of Mrs. Annie B. Moore.

Chestnut Hill Hospital, Philadelphia, \$10,000, and Episcopal Hospital of Philadelphia, \$5,000 by the will of Dr. William T. Van Pelt.

Misericordia Hospital, Philadelphia, \$1,000 by the will of Mrs. Katherine L. Farrell.

Pennsylvania Hospital, Philadelphia; Allegheny General Hospital, Pittsburgh; Trudeau Sanatorium, Trudeau, N. Y.; one fourth each of the income from an estate of \$822,160 left in trust by Mrs. Lillie Ingham Baker in 1931. The remaining fourth is to be distributed to various hospitals at the discretion of the trustees to help defray expenses of persons desiring the use of private rooms but unable to afford the entire charge.

St. Luke's and Children's Hospital, Philadelphia, \$9,400 by the will of Miss Lucy L. Haswell.

**Medical Bills in Congress.**—Changes in Status: S. 5, the Copeland food, drugs, devices and cosmetics bill, failed to become a law. The bill, as amended by the House Committee on Interstate and Foreign Commerce, passed the House Friday, June 19, and was sent to conference. Subsequently, however, the Senate accepted the House amendments to the bill, subject

to a new Senate amendment. The bill then again was brought before the House for consideration. The Senate amendment was defeated in the House and the bill died when the Congress adjourned, sine die, June 20. S. 4390 passed the House and Senate, providing that appointments to the Medical Administrative Corps shall be restricted to pharmacists who are graduates of recognized schools of pharmacy and requiring four years of instruction for graduation, and providing that the number of such pharmacists in the corps shall not exceed sixteen.

### FOREIGN

**Society News.**—Those who wish to attend the third International Congress of Orthopedic Surgery in Bologna, September 21-25, may benefit from reductions in transportation costs if they register with the general secretary, Dr. Delchef, in Brussels, Belgium, before July 15, according to an announcement. Dr. Fred H. Albee, New York, is a vice president of the congress.

**Personal.**—Mme. Irene Joliot Curie, daughter of the discoverers of radium, has been named undersecretary for scientific research in the recently organized cabinet of the French government. Madame Joliot Curie, who from her childhood collaborated with the late Madame Curie in her research, shared the Nobel Prize in medicine in 1935 with her husband, Frederic Joliot, for their work on radium.

**International Medical Week in Switzerland.**—The Swiss *Journal of Medicine* will sponsor the second "International Medical Week" at Lucerne August 31-September 5. Among the lecturers on the provisional program are Drs. John F. Fulton, New Haven, Conn.; E. von Gröer, Lwow, Poland; Wolfgang Heubner, Berlin; Edward Mellanby, London; François Rathery, Paris; Ferdinand Sauerbruch, Berlin, and Albert Szent-Györgyi, Szeged, Hungary. The final program and other information may be obtained from the secretary, International Medical Week, Klosterberg 27, Basle.

**Jubilee Book in Honor of Dr. Lambotte.**—Friends, pupils and patients of Dr. Albin Lambotte, chief surgeon of the Stuiwenberg Hospital, Antwerp, Belgium, have arranged to publish a jubilee book in his honor. It is planned that the book will contain the history of the development of surgery of the bones and joints, to which Dr. Lambotte has contributed notably, outlined in articles by leading orthopedic surgeons from all parts of the world. It will appear in two volumes, according to an announcement. Subscriptions may be addressed to Dr. Jean Verbrugge, 75 Avenue Van Ryswick, Anvers, Belgium. The price of foreign subscriptions is 30 Belgian francs.

## Government Services

### Dr. Hall Named Chief of Zoology Division

Maurice C. Hall, Ph.D., since 1925 chief of the zoological division of the bureau of animal industry of the U. S. Department of Agriculture, has been transferred to a similar position at the National Institute of Health. Three of his associates in the bureau of animal industry, Eloise B. Cram, Ph.D., Myrna F. Jones, Ph.D., and John Bozicevich, A.M., will accompany Dr. Hall to the National Institute of Health. Dr. Hall received his degree of doctor of philosophy at George Washington University in 1915. He is 55 years of age. Benjamin Schwartz will succeed Dr. Hall at the bureau of animal industry.

### Examination for Army Medical Corps

The War Department announces an examination during the week of August 24 to qualify candidates for appointment as first lieutenants in the Medical Corps, U. S. Army, to fill vacancies to occur during the fiscal year 1937. The examination is open to all male graduates of recognized medical schools who have completed one year's internship in an approved hospital and who will not be over 32 years old at the time it will be possible to tender a commission. Boards of experienced medical officers will conduct the examinations, which will consist of a physical examination, a written examination in professional subjects and a determination of the candidates' adaptability for military service. Full information and application blanks will be furnished by the War Department on request addressed to the adjutant general. Applications will not be considered after August 10. About thirty-five vacancies will occur during the year, and in addition an increase of fifty officers has been provided for in the War Department Appropriation Act.

### LONDON

(From Our Regular Correspondent)

May 9, 1936.

#### A Bureau of Human Heredity

Some well known men, including Lord Moynihan, Sir Arthur Keith, Sir Grafton Elliot-Smith, Sir E. Gowland Hopkins and Sir Humphry Rolleston, have formed a committee to obtain support for the Bureau of Human Heredity, which was recently set up in London. In a joint letter to the *Times* they ask for \$50,000 to carry on the work for five years. They point out that problems of national health have reached a point at which the hereditary element can no longer be neglected. Medical leaders are no longer satisfied with the alleviation of disease but feel the need of fuller knowledge of heredity in connection with prevention. This applies not only to preventing the transmission of defects. It is recognized that methods of cure must vary with the type of constitution of the patient, and here information as to heredity is important. In education, in training and in choice of a career the ascertainment of innate endowments is useful. The Imperial Bureau of Plant Genetics at Cambridge and of Animal Genetics at Edinburgh have achieved much by setting up simple machinery for collecting information based on the result of research and making these available for the practical breeder. The Bureau of Human Heredity will follow these models. The signatories say that in these days of international mistrust and animosity it is refreshing to find a field in which representatives of nearly every civilized country are engaged in cooperative work. A scheme for an international clearing house of facts concerning human heredity has been evolved by a small international committee, which has delegated to its British members the task of setting up a bureau in London for the collection and distribution of all authentic information on human genetics. The signatories point out how strange it is that students of fruit flies or mice have at their command the latest information, while those similarly concerned with man can look nowhere for a complete survey of the knowledge they require.

#### The Problem of Race

At the Royal Institute Mr. Julian Huxley gave an address on "The Race Problem" in which he showed the difficulties surrounding the use of the term race as applied to man and the misuse to which it is put by politicians and others. It was obvious that the different geographic groups of the human species differed inherently from one another. The term race had usually been used to denote such distinguishable groups, but difficulties arose. In the first place, characteristics that had no genetic basis but were national, cultural and linguistic had been erroneously ascribed to race. For example, there cannot exist such a thing as an Aryan race, since the term concerns language. Again, the main obvious differences between, say, the English, the French and the Germans, are not genetic but of national and cultural origin. In the second place, modern genetics has shown that after a cross all possible combinations of the genes concerned will be produced and will then continue to recur. In the absence of selection, no even approximately uniform blend will be formed. In the third place, man is so mobile that migration and intercrossing between different groups have been occurring on a large scale since before the dawn of history. Hence nothing approximating to a pure race now exists, with the possible exception of a few remote and primitive tribes. At best, race may be legitimately used of the hypothetical major groups (black, white and yellow) into which it has been deduced that our species early became differentiated

and which may be called primary races, and of the equally hypothetical subgroups apparently produced by later differentiation of the white race into Mediterranean, Nordic and Alpine, which may be called secondary races.

At the present day there exists no important group which can properly be called a race, and the use of the term not only has no useful application but leads to confusion, both scientific and political. For groups of people genetically distinguishable from other groups, Mr. Huxley would use some noncommittal term, such as ethnic group or *ethnos*. He holds that to define race in man is scientifically impossible, since the implications of the term do not correspond with reality. As the word race has been widely used in pseudoscientific ways to justify and rationalize various political and nationalist activities, he considers it highly desirable that some international inquiry should be made which would result in an impartial scientific pronouncement on the subject.

#### The Income Tax and the Birth Rate

The new taxes of the budget not only increase the rate payable on income but also increase the allowance made for dependent children. The result is that, while the unmarried and other payers of income taxes who do not have children dependent on them will be more highly taxed, 80 per cent of those with dependent children will gain. The object is no doubt to place the greater burdens on those best able to bear them, but it might be regarded as an attempt to encourage parenthood at a time when the birth rate has been reduced to a level which means a declining population. However, the amount of tax escaped by parenthood is too small for any perceptible effect. Moreover, the declining birth rate affects all classes, even those below the income tax level. It does not seem likely that the government had any such intention in view. Encouragement of the birth rate for militaristic reasons has been adopted as a deliberate policy in some continental countries, and recently by Russia, but it has never been as much as suggested in England and would certainly be scouted by most people. In a letter to the *Times*, Mr. R. A. Fisher, Galton professor of eugenics at University College, London, points out that, while the birth rate of England is now only three fourths of that necessary to maintain the population, no reasonable estimate would place the fertility of married payers of the income tax as high as two thirds of that of the general population. Thus their rate is not half that required for replacement. They bear the economic burden of rearing and educating children as well as part of that of the working class. The general decrease of the population of this country, which is now imminent, will entail economic consequences that have not received adequate attention.

#### The Official Grading of Milk

The minister of health has issued a new milk order to improve and simplify the special designations of milk. The present designations are "certified," "grade A (tuberculin tested)," "grade A" and "pasteurized." So many grades have been found to create confusion and some of the designations do not give consumers a clear indication of the nature of the milk purchased. The number of grades is to be reduced to three: "tuberculin tested," "accredited" and "pasteurized." "Tuberculin tested" replaces the existing "certified" and "grade A (tuberculin tested)," which both come from herds subjected to a stringent test for the absence of tuberculosis. "Tuberculin tested" will in future be the only designation. This milk may, if desired, be pasteurized, when it must be sold as "tuberculin tested milk (pasteurized)." It will then have the double security of tuberculin testing (as a safeguard against bovine tuberculosis and pasteurization as a safeguard against all milk-borne diseases). "Tuberculin tested milk" will be subjected to tests for ensuring cleanliness and good keeping qualities, but, because

of the need for simplification, the specially stringent bacteriologic test applied to "certified milk" is not retained. The other characteristic of "certified milk" was that it had to be bottled on the farm. When this is done the designation "tuberculin tested milk (certified)" will be permitted.

"Accredited milk" will be subject broadly to the same conditions as the former "grade A"; i. e., it will be raw milk from cows regularly inspected by a veterinary surgeon but not tuberculin tested. It will be subjected to the same bacteriologic tests as "tuberculin tested." The designation will indicate that it comes from herds of producers enrolled under the accredited producers' scheme, of which there are now nearly 16,000. When it is bottled on the farm, "farm bottled" may be added. "Pasteurized milk" will be, as at present, milk that has been held at a temperature of 145 F. for thirty minutes.

The present method of prescribing the bacteriologic standard by a plate count test of 200,000 bacteria per cubic centimeter will be superseded by a color test recommended by the Medical Research Council, but the test for coliform bacilli will be retained.

#### Radiology in the Medical Curriculum

A committee of the Royal Society of Medicine has made an important report on the place of radium in the medical curriculum. The teaching of radiologic anatomy and attendance on lecture courses in radiology and at the x-ray department are now required only in certain medical schools. The committee has made the following recommendations: Instruction in the physics of radiation should be given in the preclinical period. Radiology should be used when practical in the teaching of anatomy, physiology and pathology. Instruction in the use of x-rays in diagnosis and of x-rays and radium in treatment should be required in the clinical period of the curriculum. This may be accomplished: 1. By combined teaching by the clinician and radiologist. 2. By the radiologist conducting demonstrations in the x-ray department on selected films. Physicians and surgeons should attend these demonstrations and take part in the discussions. 3. By including lecture demonstrations by a radiologist in the course of lectures on medicine and surgery. 4. By forming an exhibition of roentgenograms illustrating clinical cases. The scheme to be adopted is left to the individual schools, but a combination of 1 or 2 with 3 and 4 is considered most satisfactory.

#### The Etiology of Phlyctenular Keratitis

At the Ophthalmological Society Arnold Sorsby, Richard Hamburger and R. L. Benham communicated an important paper on the vexed question of the etiology of phlyctenular keratitis. Their researches on a large scale at the White Oak Hospital, Swanley, show a positive Mantoux reaction in 80 per cent of cases. They also made an exhaustive survey of the literature. They conclude that the phlycten is a nonspecific reaction of the conjunctiva and conjunctival layer of the cornea—probably of anaphylactic nature. In something like 75 per cent of cases the state underlying the reaction is a tuberculous infection that occurs at an earlier age than in the normal child population. As in the latter, the infection is overcome in the great majority of cases. Because they are infected with tuberculosis earlier in life, phlyctenular cases give a greater quota of tuberculous disease than normal children. (The course of tuberculosis depends much on the age at which the patient is infected.) In a series of 238 cases followed from five to ten years, the subsequent incidence of tuberculous disease was ten times the notification rate for children of the corresponding age groups. The authors conclude that phlyctenular keratitis is not a manifestation of tuberculous disease but of tuberculous infection. Other factors than tuberculous infection can produce the phlyctenular reaction.

### Danger of Vaccination Against Brucellosis with Living Vaccines

At the April 7 meeting of the Académie de médecine of Paris, veterinarians Velu and Zottner called attention to the fact that the use of living vaccines rendered the diagnosis of brucellosis in animals very difficult. Another contribution to the subject was presented at the April 21 meeting of the same society by Merliac and Lisbonne under the title "A Case of Undulant Fever of Bovine Origin: Danger for Human Beings of Animal Premunition with Living Vaccines." A woman, aged 52, wife of a farmer, complained in September 1935 of headache and lumbago, which had not improved after ordinary treatment. The only objective finding was a persistent rise of temperature (100-102 F.) accompanied by profuse sweats. The Widal test for typhoid was negative when the patient was first seen two months after the onset, but the blood showed a positive Wright reaction in a dilution of 1 to 250; hence the suspicion of an undulant fever was confirmed. Bacilli showing the typical reactions of *Brucella abortus-bovis* were found November 18 in the blood culture. After a prolonged febrile period the patient was considered as cured at the time the paper was read. Careful inquiry elicited the fact that no other cases of brucellosis had been reported from the section of country in which the patient had lived for many years.

A guinea-pig was inoculated with the milk of a cow which the patient had taken care of. Cultures of the blood of the guinea-pig also revealed the presence of *Brucella abortus-bovis*. The bacilli isolated from the patient's blood and that of the guinea-pig were found to possess identical properties (ability to produce hydrogen sulfide. The cow had been kept isolated from all other animals and had never aborted, wherefore the question arose as to how the brucella infection had occurred. On inquiry it was found that the cow had been given two prophylactic (premunition) injections of living brucella vaccines in 1933. Specimens of this vaccine were also found to possess the same property, which is atypical for *Brucella abortus-bovis* to produce hydrogen sulfide. Thus the three mediums (blood of patient, that of guinea-pig and the vaccine) possessed identical properties and the chain of evidence seems to be complete that the living vaccine infected the cow and, in turn, the patient.

At the 1934 congress of hygiene one of the authors, Lisbonne, as also Taylor and Vidal, called attention to the fact that undulant fever had been contracted by veterinary surgeons who had been accidentally inoculated by living vaccines; therefore the use of these in the prevention of "epizootic abortion" ought to be carefully controlled. The case reported by Merliac and Lisbonne shows that a living vaccine can be harmful not only by direct inoculation but by an intermediary, such as an infected animal.

Much care should be employed in selecting strains of bacilli for use as living vaccine. Only those which a number of experiments have shown to be attenuated should be used. Such a research is not easily accomplished. The use of living vaccines, at least in France, is not subject to the control which it merits. The indirect danger to human beings, as illustrated by this case, is one that cannot be minimized.

#### Acute Endocarditis Due to Bacillus of Pfeiffer

At the meeting of the Société médicale des hôpitaux of Paris, April 3, Lesne and his associates added another case of severe generalized infection, with an endocardial origin, due to the bacillus of Pfeiffer. A girl, aged 15 years, had been taken suddenly ill six days before admission to the hospital. At the onset, following emesis, a chill was noted followed by high temperature, which persisted without chills but was accom-

panied once by epistaxis. Soon after admission, the clinical picture appeared to be that of an endocarditis of probable rheumatic origin. A splenomegaly was noted. Three blood cultures were negative. About three weeks after admission, the clinical picture became that of acute septicemia, with recurrent chills, sweats and high temperatures and symptoms like those of a splenic infarct. Hemocultures during these three weeks revealed on two occasions the presence of a filament-like gram-negative bacillus, which was identified by Legroux of the Pasteur Institute as the bacillus of Pfeiffer. Symptoms of an acute nephritis appeared toward the end of the fourth week following the recurrence of chills and the girl died with the symptoms of a uremic coma.

The bacillus of Pfeiffer found in the blood was very difficult to reinoculate on culture mediums, but this was finally accomplished.

### Compulsory Antidiphtheria Vaccination

At the same meeting Poulain quoted from the statistics of a large city, St. Etienne, in Central France on the value of prophylactic vaccination with the Ramon antitoxin in preventing the spread of diphtheria. An epidemic occurred in one of the suburbs, which involved from 8 to 10 per cent of the school children. The epidemic did not extend to St. Etienne, but nevertheless there were a number of cases in the city itself. Thirteen of these occurred in 1,000 nonimmunized children while one case was observed among 5,000 who had been vaccinated. Faced with the danger of extension of the disease and the fact that from 15 to 20 per cent of the children had not been vaccinated, an appeal was made to all parents to have all children immunized who had not received the anatoxin and to have all those already vaccinated subjected to another vaccination. This campaign was successful beyond all expectations, resulting in from 90 to 95 per cent of all school children now being vaccinated. From 60 to 70 per cent of these have received ninety anatoxic units.

Observations during the past seven years at St. Etienne have permitted the following conclusions:

1. A proportion of 80 per cent vaccinated children is sufficient to prevent a widespread extension of an epidemic but permits small centers of infection to exist which become a serious menace if there is a decrease in the number of vaccinated children.
2. To keep up a high percentage of vaccinated children a constant propaganda to secure written permission of the parents is essential.
3. In vaccinations consisting of only two injections occasional but benign cases persist.

To cause diphtheria to disappear completely, antidiphtheria vaccination should be made obligatory, at least in cities, before admission to schools. A second vaccination should be given one or two years later.

### Coagulation of the Blood

At the Dec. 11, 1935, meeting of the Société française d'hématologie, Nolf of Brussels stated that in spite of numerous efforts made to explain the physiology of coagulation the causes still may remain obscure. The theories generally accepted are far from being proved, so that much confusion still exists. Does the plasma contain all the elements essential to the formation of fibrin and thrombin or is the plasma in a pure state, according to the classic theory, noncoagulable because it lacks an essential element which the leukocytes and blood platelets furnish? Antithrombin is elaborated in the liver. Antithrombin disappears during coagulation and it is this digestion or consumption of the antithrombin which is the first stage of coagulation. The thrombin is said to be a product of a substance termed prethrombin, but Nolf does not believe that thrombin should be applied to a definite chemical entity;

rather one must apply the term thrombin to an ensemble of nonsaturated complexes of fibrinogen which appear during the act of coalescence of colloidal particles, termed coagulation of the plasma. Thrombin is not the result of the transformation of a single substance, prothrombin, but is formed by the union of two protein constituents of the plasma, the thrombozyme and the thrombogen.

The recent work of Gengou on the coagulating action of staphylococci on the plasma amply confirms Nolf's views. The intervention of fibrinogen favors the union of thrombozyme and thrombogen and in very stable liquids permits formation of thrombin. This permits the abandonment of the classic theory of coagulation occurring in two steps and its replacement with a one step process. Fischer in his studies on coagulation in birds has shown that the formation of fibrin does not await the moment when all the necessary thrombin has been formed but begins immediately.

Nolf maintained that coagulation seems essentially to be an autocatalysis.

### Prophylaxis of Contagious Diseases in France

The chairman, Professor Lemierre, of the Special Committee of the Academy of Medicine, gave the report for 1934. Typhoid existed in practically every department (county) of France, in isolated cases or in epidemics that were sharply localized. Some ascribe the recrudescence of the disease to the drought which existed during the greater part of 1934, so that people were obliged to seek water far from their homes at polluted sources. The ingestion of clams at seaside resorts was responsible for a large number of cases. In spite of warnings and legal procedures, the shores from which shellfish of all kinds are obtained continue to be found too near the outlet of sewers. This is especially true of Toulon, the principal French naval base. Vaccination has greatly diminished the incidence of typhoid, but unless made compulsory, as in the case of those entering military or naval service, its prophylactic value is ignored by the average citizen.

Variola is practically nonexistent in France. Occasionally, cases are found, as recently at Reims, in those coming from other parts of Europe. The benefits of vaccination are well illustrated by the diminution of variola in Algiers, a large French colony. In 1927, 4,000 cases of variola were reported, whereas in 1934 there were only nineteen cases.

Measles is perhaps the most common of all the contagious diseases in France.

The incidence of diphtheria has been greatly lessened as the result of an organized campaign to use the Ramon anatoxin as a vaccine. Some cases of diphtheria occurred in vaccinated children. This emphasizes the necessity of revaccination if the Schick reaction remains positive. This was the case in 1934 in 40 per cent of 250 children who had been given three injections of the anatoxin in 1933.

Isolated cases of cerebrospinal meningitis were reported from fifty-four of eighty-eight departments. The search for carriers always resulted negatively; hence prophylactic measures are impossible at present. The mortality was very high, 47 per cent of eighty-five reported cases, despite early specific treatment.

Isolated cases of poliomyelitis were reported from fifty-seven of eighty-eight departments. There were seventy-one cases with twenty-two deaths in the Paris region. No progress was made in clearing up the manner in which the infection spreads.

There was ample evidence of an increase in the incidence of undulant fever. It was reported from forty-two of eighty-eight departments, located in all parts of France. *Brucella melitensis* was responsible for practically every case. The atrium of infection was most frequently through skin abrasions, less so as the result of drinking unboiled milk or of eating fresh cheese. Brucellosis in human beings and in animals are closely allied,

although due to different types of the *Brucella* organisms. Efforts are being made to immunize those whose occupations bring them into contact with animals who are carriers or are infected by organisms of the *Brucella* type.

## BERLIN

(From Our Regular Correspondent)

### The Sick Insurance Societies During 1934 and 1935

The final figures on the work of the sick insurance societies during the years 1934 and 1935 have been made available. The number of such organizations tends to decrease as the result of mergers of the smaller societies. In 1914 sick insurance societies in the German reich numbered more than 10,000; in 1934 there were barely 6,000. The total membership in 1934

TABLE 1.—Type of Assistance in Sick Aids

Type of Aid	Amount Expended in Reichsmarks
Medical treatment .....	330,683,000
Dental treatment .....	98,163,000
Medicaments and therapeutic accessories.....	158,976,000
Hospital care .....	224,548,000
Sick benefits in cash.....	224,121,000

amounted to nearly 20,000,000 persons, of whom 13,000,000 were males. The number of cases in which the societies according to statute became liable for payment of claims increased from 35,000,000 in 1932 to 46,400,000 in 1934. The insured himself received the benefit in 31,700,000 of the cases for 1934, and relatives of the insured in 14,700,000 cases. Two

TABLE 2.—Average Amount per Member Expended by Sick Insurance Societies

Year	Amount	Year	Amount
1929 .....	20.86 RM	1932 .....	16.50 RM
1930 .....	20.66	1933 .....	16.26
1931 .....	18.61	1934 .....	16.57

factors are responsible for the increased morbidity: 1. Persons who had been unemployed for a long time were not equal to exacting occupational requirements and hence were more susceptible to illness. 2. Many persons, fearful of losing their jobs if they reported sick, failed to report. The danger of these eventualities has lessened with the improvement in the

TABLE 3.—Disbursements According to Type of Organization

Class of Insurance Organizations	Total Expenditure for Doctor's Fees in Reichsmarks	Total Membership	Expenditure per Member in Reichsmarks
Municipal .....	179,462,000	12,124,000	14.80
Rural .....	20,732,000	1,802,000	11.50
Industrial .....	54,734,000	3,002,000	18.25
Guild (innung) .....	7,738,000	529,000	14.63
Miners .....	10,605,000	564,000	18.80
Supplementary (ersatz) ..	56,547,000	1,878,000	30.11

labor market. This improvement has also brought about an increase in the number of insurance holders even among the upper age groups. In 1934, 6,800,000 cases of illness led to temporary working disability; in 1933 there were 5,400,000 such cases. On the other hand, the average duration of illness declined from 29.3 days in 1932 to 24.6 days in 1934.

The number of cases in which obstetric care was paid for increased about 32.7 per cent, from 574,515 cases in 1933 to

762,428 in 1934. The number of fatalities rose from 137,670 to 146,191, because of an increase in the number of older workers employed.

Both income and expenditures of the sick insurance societies increased during 1934. Gross income amounted to nearly 1,300,000,000 reichsmarks, or 62.10 reichsmarks per member. Disbursements increased from 1,181,000,000 reichsmarks to 1,314,000,000 reichsmarks; that is, an increase per member of from 63.69 to 65.89 reichsmarks.

TABLE 4.—Expenditures per Member

	Reichsmarks
Treatment by approved physicians.....	15.37
Dental treatment .....	4.68
Medicaments and other therapeutic adjuncts.....	8.08
Hospital care .....	11.67

The sum of 1,055,000,000 reichsmarks was expended for sick aids; its distribution according to type of assistance is given in table 1.

All the sick insurance societies (including the ersatz, or supplementary societies) expended the average amounts per member from 1929 to 1934 given in table 2.

The amount disbursed in physicians' honorariums differed considerably according to the type of organization, as table 3 illustrates.

TABLE 5.—Increase in Disbursements from 1933 to 1934

Medical treatment .....	2.0 per cent
Dental treatment .....	8.8 per cent
Medicaments and so on.....	9.6 per cent
Hospital care .....	1.6 per cent

For obstetric care, 122.40 reichsmarks per member was expended; for death claims 84.77 per insured person. Administrative costs amounted to 135,100,000 reichsmarks.

Unencumbered assets of the organizations, despite a decrease of some 17,900,000 reichsmarks, still totaled 818,700,000 reichsmarks. Reserve funds decreased by around 35,500,000 reichsmarks; they were however, with 402,300,000 reichsmarks, double the amount stipulated by law.

TABLE 6.—Income of Members in Billions of Reichsmarks

1929.....	31.6	1933.....	18.5
1930.....	29.5	1934.....	21.1
1931.....	24.0	1935.....	22.2
1932.....	18.5		

According to official monthly reports, the number of insurance societies was considerably decreased during 1935. On Jan. 1, 1936, there were barely 5,000 such organizations, as against more than 21,000 in 1913.

The total membership amounted to around 20,800,000 on Oct. 31, 1935, against 17,800,000 at the beginning of 1933. Cases of illness involving impaired working capacity increased in number from 7,400,000 in 1934 to 8,000,000 in 1935. This was due to the factors that have been adduced. The influenza patients are also included in the 1935 total.

Total expenditures (1,272,600 reichsmarks) exceeded the total income by around 57,600,000 reichsmarks. The per member expenditures in 1935 by the legally authorized societies are given in table 4.

Expenditures for these services increased in varying degree: for medicaments the increase was 9.3 per cent; for dental treatment, 5.2 per cent; for hospital care, 3.5 per cent, and for medical treatment, 1.3 per cent.

Disbursements for the same purposes increased from 1933 to 1934 as in table 5.

It will be noted that the cost of treatment by approved physicians showed a modest increase from 1933 to 1935.

The personal administrative costs increased 3.2 per cent per member, the material costs 5 per cent per member. Gross income increased around 4.5 per cent. The National Bureau

TABLE 7.—*Fluctuations of Average Income*

1929.....	1,508 RM	1933.....	1,099 RM
1930.....	1,452 RM	1934.....	1,165 RM
1931.....	1,263 RM	1935.....	1,180 RM
1932.....	1,083 RM		

of Statistics attributes this to an increase in the incomes of members. In table 6 the total income of all the members from 1929 to 1935 is given in billions of reichsmarks.

The average income per member showed the fluctuation given in table 7.

(From Our Regular Correspondent)

April 15, 1936.

#### Some Problems of Physicians

The first reunion of the *Corporazione delle professioni e delle arti* was recently held in Rome under chairmanship of the head of the government. The vice president of the corporation observed that the free activities of the medical profession come to a standstill whenever new institutions of the nature of the *Casse Mutue Sanitarie* (centers for medical care of insured workers) are opened. He stated that in order to protect medical practice it is necessary to review the plans of the several branches of medicine, to establish restricted and special functions for each different branch and to make compulsory the registration of practitioners in the book for that purpose. The new national medical fees were discussed. The National Syndicate of Physicians suggested a plan of fees in which there is a tendency to standardize the fees of the several provinces and to fix a minimal fee without indicating the maximal charges, excluding from the fee the medical attendance given by specialists, regular professors and university professors. The following are the charges proposed: visits for consultation and care of the patient at his own home, 20 lire (\$1) if it is only one visit and 15 lire (\$0.75) if there are several consecutive visits. The charges for visits for consultation and care of the patient at the physician's office will be 15 lire (\$0.75) for only one visit and 10 lire (\$0.50) for several consecutive visits. Consultations in emergencies will be charged with 25 lire (\$1.25) if during the day and 40 lire (\$2) if during the night.

#### Influenza and Tuberculosis

The *Federazione per la lotta contro la tubercolosi* recently discussed the influence of influenza on development of tuberculosis. Professor Ramoino stated that influenza prepares the terrain for the development of common chronic catarrh, which predisposes the organism of the patient to the development of tuberculosis.

Professor Manara emphasized the importance of establishing, with precision, the clinical picture of sporadic influenza in order to differentiate these types of influenza from tuberculosis when the latter follows an atypical evolution.

Professor Maragliano has seen a large number of cases of pulmonary tuberculosis, in more than half of which the evolution of the disease was related to an attack of influenza. As a rule the postinfluenzal symptoms are so trivial that they are not noticed. There is slow but progressive loss of weight, slight fever in the evenings, weakness, and incapacity for physical and mental work. Cough and other symptoms which erroneously have been considered as early symptoms of

pulmonary tuberculosis are absent. If the patients are seen early in the development of the disease, both clinical and roentgen examinations fail to prove the presence of tuberculosis. Early diagnosis is possible, however, in this type of pulmonary tuberculosis by estimating the symptoms given by the tuberculous toxemia, the evaluation of which is of importance in controlling further development of the disease.

#### Selection of Physicians by Insured Workers

An agreement was recently made for the medical and surgical care of insured workers in the *Casse Mutue dei lavoratori de l'industria*. As a rule the consultations and treatment of the patients will be made in the clinics for ambulatory patients, except in cases in which the patients are in such a condition as to be unable to go to the ambulatory clinic. In the latter event the patients will be seen and treated at home. Insured workers are free to select their own physicians, either from those of the group of municipal physicians or from those who have a private clientele; but after having chosen a physician they cannot change to another during an illness. Physicians who practice in connection with the insurance societies will be registered in a special provincial book of registration. Enforcement of the standards established in the agreement will be in the hands of a committee.

#### Surgical Society Meeting

Professor Finsterer of Vienna spoke on surgery of the large intestine recently before the *Società Piemontese di chirurgia*. Surgical indications in constipation are restricted to grave cases after failure of diet and medical treatments if cathartics administered cause intense pain to the patient. The speaker never resorted to the performance of anastomosis in treating either spastic constipation or megacolon. In some grave cases of spastic constipation, simple distention of the anal sphincter, either hypertrophic or with anal fissure, has resulted in cure with regression of a marked dilatation of the sigmoid flexure of the colon. The anal sphincter should be investigated before a decision is made to perform any operation in cases of constipation. Resection of the sigmoid flexure is indicated in megasigmoid in cases in which the formation of valves in the flexure are the main cause of constipation. The speaker, in performing hemicolectomy, removes the half of the colon up to the pelvic colon. The elimination of general anesthesia for the operation and the use of laterolateral anastomosis are the factors that account for the satisfactory results obtained.

Professor Uffreduzzi spoke on postanastomotic peptic ulcer. The nature of the postanastomotic scar is related to the constitution of the patient. Innervation disturbances with paralysis of the anastomotic loop or with spasms of either the afferent or the efferent loops may take place in the new formed pylorus. Frequently these disturbances are caused by the presence of a peptic ulcer located at either the gastric or the jejunal anastomotic ends or in the jejunum at a certain distance from the anastomosis. Postanastomotic peptic ulcers may follow a long evolution without grave complications. Surgery is the only indicated treatment. The speaker classified his patients in seven groups according to the type of operation performed.

## Marriages

HENNING W. MATHIASSEN, Persia, Iowa, to Miss Rita Rose Dougherty of Manilla in Des Moines, May 25.

DONALD MUNRO MACINTOSH JR., Old Fort, N. C., to Miss Ruth Ellen Gish of Philadelphia, May 6.

CARL D. OELRICH, Sioux Center, Iowa, to Miss Thelma Mae Austin of Albany, Mo., May 15.

JOEL ERNEST GOLDTHWAIT to Mrs. Phillip Leverett Saltonstall, both of Boston, April 30.

CARL V. MORRISON, Grinnell, Iowa, to Miss Dorothy Nafus of Nashua, April 25.

## Deaths

**James Tate Mason** ☉ Seattle, President of the American Medical Association, died, June 20, at the Virginia Mason Hospital, of endocarditis with multiple emboli, aged 54. Dr. Mason was born in Virginia, May 20, 1882, the son of Dr. Claiborne Rice Mason of Lahore, Orange County, Va. After graduating from the University of Virginia Department of Medicine, Charlottesville, in 1905, Dr. Mason engaged in the practice of surgery first at Philadelphia, then at Franklin, Wash., and finally at Seattle, where he had practiced continuously since 1909. From 1916 to 1920 he was surgeon and superintendent of the King County Hospital. Since 1920 he had been chief surgeon to the Mason Clinic and president of the Virginia Mason Hospital. He was consulting surgeon of the United States Marine Hospital, Seattle, the American Mail Line, the Alaskan Steamship Company and the Northern Pacific Railroad Company. Dr. Mason was a member of the House of Delegates of the American Medical Association for six years, between 1928 and 1934; he was secretary of the Section on Surgery, General and Abdominal, from 1923 to 1926, when he was elected chairman, serving in that capacity for one year. Dr. Mason was past president of the Pacific Coast Surgical Association, and in 1930 vice president of the American Association for the Study of Goiter; a member of the American Surgical Association, Southern Surgical Association, Western Surgical Association, and the North Pacific Surgical Association, and fellow of the American College of Surgeons. He was at one time a county coroner and a member of the state board of health.

Tate Mason was a genial, friendly man, much beloved by all who knew him. He was a builder, a true leader. During his term as President-Elect he traveled widely on behalf of the Association, notwithstanding ill health and the pressure of his own affairs. During the Kansas City session, although imminently confronted by impending death, he kept in intimate touch with the progress of affairs, made the necessary appointments and urged the promotion of high standards and high ideals. By his death, American medicine loses a leader, chosen for its highest honors, who demonstrated by his life and by his death how well he merited this recognition.

**William Hemple Arthur** ☉ Brigadier General, U. S. Army, retired, Washington, D. C.; University of Maryland School of Medicine, Baltimore, 1877; member of the House of Delegates of the American Medical Association in 1915; entered the army as an assistant surgeon in 1881; commander of a hospital ship during the Spanish-American War; served with the China Relief Expedition in 1900 and in the Philippines; in 1908 was promoted to lieutenant colonel and in 1911 colonel; appointed commandant of the Army Medical School in 1915; served during the World War; was retired as a brigadier general under the Act of June 21, 1930; fellow of the American College of Surgeons; formerly emeritus professor of military surgery, Georgetown University School of Medicine; at one time medical director of the Georgetown University Hospital; aged 80; died, April 19, in the Walter Reed General Hospital.

**Henry Hawkins Tyson** ☉ New York; University of the City of New York Medical Department, 1887; at one time instructor in ophthalmology, Columbia University College of Physicians and Surgeons; member of the American Ophthalmo-

logical Society; fellow of the American College of Surgeons; past president of the New York Ophthalmological Society; during the World War, eye examiner for the third district of the New York Draft Board; ophthalmic surgeon to the Herman Knapp Memorial Eye Hospital; ophthalmologist to the Sea Breeze Hospital, Brooklyn, and the Letchworth Village, Thiells; assistant in the eye department at the Vanderbilt Clinic; author of numerous monographs on ophthalmologic subjects; aged 70; died, April 18.

**Edgar Warden Phillips** ☉ Rochester, N. Y.; Cornell University Medical College, New York, 1911; assistant professor of surgery, University of Rochester School of Medicine; fellow of the American College of Surgeons; member of the American Association for Thoracic Surgery; attending surgeon to the Rochester General Hospital, surgeon to the Monroe County Tuberculosis Sanatorium and consulting surgeon to the Rochester State Hospital; aged 47; died, May 5, of lobar pneumonia.

**William Clifton Lyle**, Carrollton, Ga.; University of Georgia Medical Department, Augusta, 1893; member of the House of Delegates of the American Medical Association, 1911, 1914 and 1922; fellow of the American College of Surgeons; for many years secretary of the Medical Association of Georgia; formerly professor of otology at his alma mater; served during the World War; aged 64; died, April 15, of cardiovascular renal disease and arteriosclerosis.

**George Whitfield Stephens** ☉ Melrose, La.; Tulane University of Louisiana Medical Department, New Orleans, 1907; member of the New Mexico Medical Society and the American Psychiatric Association; served with the British Army during the World War; formerly superintendent of the New Mexico Home and Training School for Mental Defectives, Los Lunas; aged 57; died suddenly, April 26, in a hotel at New Orleans, of heart disease.

**Wells Teachnor Sr.** ☉ Columbus, Ohio; Medical College of Ohio, Cincinnati, 1892; member of the House of Delegates of the American Medical Association in 1924 and 1925 and from 1927 to 1936; past president of the Ohio State

Medical Association; fellow of the American College of Surgeons; member of the staff of the Hawkes Hospital of Mount Carmel, now known as the Mount Carmel Hospital; aged 66; died, June 12.

**Clarence Eugene Simonds**, Willimantic, Conn.; University of the City of New York Medical Department, 1897; member of the Connecticut State Medical Society; fellow of the American College of Physicians; served during the World War; chief physician, obstetrician and president of the medical and surgical staff of the Windham Community Memorial Hospital; aged 62; died, April 1.

**Robert James Marshall**, East Liverpool, Ohio; Western Reserve University Medical Department, Cleveland, 1886; member of the Ohio State Medical Association; formerly mayor and member of the city council; on the staff of the East Liverpool City Hospital; aged 73; died, March 2, of cerebral hemorrhage.

**Frank Lester Todd**, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1891; member of the Medical Society of the State of Pennsylvania; fellow of the American College of Surgeons; member of the consulting staff of the Presbyterian and Allegheny General hospitals; aged 74; died, April 17, in the Conway (S. C.) Hospital, of pneumonia.

JAMES TATE MASON, M.D., 1882-1936

**Henry Strauss Wieder** \* Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1902; associate professor of otology, University of Pennsylvania Graduate School of Medicine; on the staff of the Northern Liberties Hospital; aged 54; died, April 22, of fracture of the fibula and pulmonary embolism following a fall.

**Charles Augustus Vosburgh** \* St. Louis; Barnes Medical College, St. Louis, 1904; member of the Radiological Society of North America; past president of St. Louis City Medical Society; served during the World War; formerly professor of clinical surgery and surgical pathology at his alma mater; aged 57; died, April 19, of heart disease.

**Earl Roach McCarthy** \* Chicago; Rush Medical College, Chicago, 1922; fellow of the American College of Surgeons; formerly clinical instructor in surgery at his alma mater; aged 40; on the staffs of the Cook County Hospital and the Presbyterian Hospital, where he died, April 21, of malignant nephrosclerosis and uremia.

**Harry Samuel Lane** \* Kansas City, Mo.; University Medical College of Kansas City, 1908; member of the Associated Anesthetists of the United States and Canada; medical director of the Fairmount Maternity Hospital; aged 60; was killed, April 14, in an automobile accident.

**Russell Ellis Minter**, Borger, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1926; member of the State Medical Association of Texas; past president of the Hutchinson County Medical Society; aged 36; died, March 18, of agranulocytosis.

**John Nevin** \* Jersey City, N. J.; University of the City of New York Medical Department, 1886; formerly medical director of the Jersey City Hospital; for many years police surgeon; aged 72; died, April 26, of cerebral hemorrhage.

**Henry William Norrish**, Logan, Kan.; Ensworth Medical College, St. Joseph, 1894; Missouri Medical College, St. Louis, 1895; member of the Kansas Medical Society; aged 66; died, March 15, of cardiovascular renal disease.

**Louis Maddock**, San Andreas, Calif.; Jefferson Medical College of Philadelphia, 1893; aged 67; died, March 25, in Stockton, of coronary occlusion, arteriosclerosis and injuries received when he fell down the stairs.

**James Claude Woodward**, Los Angeles; Lincoln (Neb.) Medical College of Coter University, 1900; aged 58; died, March 30, of carcinoma of the parotid gland with metastases to the liver, spleen and kidneys.

**Thomas Allen McCormick** \* St. Albans, Vt.; University of Vermont College of Medicine, Burlington, 1915; on the staff of St. Albans Hospital; aged 46; died, March 28, of a self-inflicted bullet wound.

**Edith Lyall Maddren Mosher**, Dupree, S. D.; National University Medical Department, Washington, D. C., 1899; aged 59; died, March 10, in Rapid City, of intestinal obstruction.

**Simon Leo Wissig**, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; aged 62; died, March 21, of chronic myocarditis.

**Albert Willis**, Metropolis, Ill.; St. Louis College of Physicians and Surgeons, 1904; member of the Illinois State Medical Society; aged 54; died, March 6, of diabetes mellitus.

**Andrew Jackson Morris**, Newton, Ala.; Southern Medical College, Atlanta, Ga., 1887; member of the Medical Association of the State of Alabama; aged 73; died, March 15.

**Charles Louis Marotte** \* Trenton, N. J.; Georgetown University School of Medicine, Washington, D. C., 1930; aged 31; died, March 17, in St. Francis Hospital.

**Harold Everett Smiley**, Providence, R. I.; Harvard University Medical School, Boston, 1922; pathologist to the Charles V. Chapin Hospital; aged 45; died, March 27.

**Andrew Murphy Jr.**, Mohawk, N. Y.; University and Bellevue Hospital Medical College, New York, 1901; aged 58; died, March 15, of carcinoma of the rectum.

**Robert T. A. Nixon**, Brookfield, Wis.; Detroit College of Medicine, 1903; aged 57; was instantly killed, March 31, when his automobile was struck by a train.

**Clifton Horace Frizelle**, Chicago; College of Physicians and Surgeons, Keokuk, Iowa, 1889; aged 67; died, March 23, in Elgin, Ill., of arteriosclerosis.

**Emett Lucien Siver**, Chicago; Fort Wayne (Ind.) College of Medicine, 1884; aged 76; died, March 6, of carcinoma of the urinary bladder.

**Henry P. Hart**, Chicago; Rush Medical College, Chicago, 1891; aged 71; died, March 21, of chronic myocarditis.

## Correspondence

### INEFFICIENCY OF GARGLES

*To the Editor:*—In a communication published in *THE JOURNAL*, May 9, page 1679, Kaunitz criticizes—rightly, I think—the technic by which investigations of the efficacy of the “gargle” have been carried out. I fully agree with his conclusions.

Some ten years ago I investigated this question by having ten patients gargle with a solution of methylene blue after administration of atropine. An examination made immediately afterward showed that in no case had the fluid reached the tonsils, the posterior pharyngeal wall, the posterior part of the soft palate or the uvula. In most cases the dye stained only the anterior half of the soft palate. From this investigation I reached the conclusion that gargling was entirely useless as a method of introducing an antiseptic medication to the tonsil or pharynx.

H. M. WALKER, M.D.,  
145 Harley Street, W. 1, London, England.

### DIPHTHERIA WITH SCARLET FEVER

*To the Editor:*—In reading the communication of Dr. Alexander Zabin, in *THE JOURNAL*, May 2, page 1588, I was struck by his statement that “diphtheria coexistent with scarlet fever is about one in every ten thousand cases.” I had always considered it far more common.

While it is true that diphtheria complicating scarlet fever is not frequent during the first or even the second week of the disease, being usually a complication of convalescence and as such being referred to usually as “postscarlatinal diphtheria,” it is nevertheless a not uncommon complication at any stage. As a matter of fact, Schamberg and Kolmer state that in a series of 1,259 cases of scarlet fever in which routine throat cultures were taken before or after admission to the Philadelphia Hospital for Contagious Diseases 285, or 29.25 per cent, showed diphtheria-positive cultures. Certainly the coexistence of these two diseases cannot be regarded as a rare complication.

As for the statement that “the immunity conferred by toxin-antitoxin or toxoid is only relative and not absolute,” it is of course known that cases of diphtheria have occurred in children with negative Schick tests, although there is always the possibility of an error in technic in performing the test.

SANDOR A. LEVINSOHN, M.D., Paterson, N. J.

### TUBING FOR DRAINAGE OF THORACIC CAVITY

*To the Editor:*—In the Therapy of the Cook County Hospital (*THE JOURNAL*, May 16, p. 1728) I see that reference is made to the use of red rubber tubing in the drainage of spaces within the thorax, because it is opaque to x-rays and films can therefore be made for information and record.

The usual red rubber tubing, however, is too hard for safety in this part of the body, and for that matter in several other regions also. In the chest, which is in constant motion, the pressure and friction of a stiff tube has produced many serious complications; for example, hemorrhage, bronchial fistula extension of a suppurative process, and extension of infection to the mediastinum and its organs.

There is at least one form of red rubber tube which has not these disadvantages, but this is not radiopaque. A pro-

cedure which I think far preferable is to use tubes of soft, virgin gum, usually black, and when I wish to outline or otherwise observe the conditions within the drained cavity, I slip a small catheter or other opaque rubber tube through the drainage tube as far as may be necessary, and immediately after the x-ray exposure has been made it is withdrawn. This method is also preferable to the injection of opaque fluid into a drained cavity.

HOWARD LILIENTHAL, M.D., New York.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### DIETS FOR BOYS IN CAMPS

*To the Editor.*—A camp houses and feeds about 200 youngsters between the ages of 17 and 28. The ration allowance is a shade less than 50 cents a day. On this money it is possible to feed satisfactorily as far as quality and tastiness are concerned. The quantity also is sufficient. However, in winter the ration allowance does not permit the buying of any considerable quantity of fresh vegetables or other kinds of "roughage" and, as a result, the boys often suffer from constipation. Canned fruits and vegetables are available but the cooks, although thoroughly experienced and well qualified, do not seem to have the knack of preparing these in a sufficiently palatable way to overcome the urge for "meat 'n' spuds" on the part of the enrollees. Any suggestions you may make or any special cook book you may recommend will be greatly appreciated. I assure you. Would the limiting of the quantities of meat and potatoes on the table help sufficiently to warrant instituting the measure? Kindly omit name and address.

M.D., Michigan

**ANSWER.**—Young men between the ages of 17 and 28 require a varied diet, including fruits and vegetables. The fresh vegetables may be served raw or in salads. The canned vegetables may be used in soups, scalloped dishes and stews or baked with cheese. Young men as a rule like cheese. The canned fruits may be served with cake or with puddings, such as cornstarch or tapioca pudding. Cornstarch pudding topped with canned berries such as loganberries, strawberries or raspberries is a very popular dessert. Dried fruits, such as raisins or dates, may be cooked in with the breakfast cereal.

The October 1935 issue of *Scouting*, the Boy Scout magazine, has some excellent suggestions for camp menus "Large Quantity Cookery" by Richard and Trent (Boston, Little, Brown & Co) has many interesting recipes.

### SPINAL FLUID TEST FOR INFANTILE PARALYSIS

*To the Editor.*—In making a spinal fluid test for infantile paralysis, how is the test made? What does it show? How soon after exposure will it show? Is the test positive? What is the standard treatment at present? What is your opinion of the treatment of a young patient who was sick for three or four days? Paralysis developed, and a blood transfusion was given from the mother, who had never had infantile paralysis. No other treatment was given. About twelve hours later the patient was considered out of danger. Please omit name.

M.D., Washington

**ANSWER.**—When spinal fluid is obtained by lumbar puncture, the degree of pressure and the clarity are observed. For proper interpretation there should be an absence of traumatic blood.

Further examination of the spinal fluid should include a cell count on a hemocytometer to determine the number of cells per cubic millimeter. A Pandy test for globulin should be made and also a Ross-Jones test for albumin. In addition, a quantitative test (modified Folin-Wu) for sugar, which should be normal in poliomyelitis. A differential cell count must be done.

In poliomyelitis, the spinal fluid is usually under increased pressure and its transparency is about the same as with normal fluid. Lymphocytes predominate, from 90 to 95 per cent often, except in the very early stage of the disease. The total number of cells should exceed 10 per cubic millimeter in any case of poliomyelitis. Abnormalities in the spinal fluid will not allow exposure of the patient to infantile paralysis unless the patient contracts the disease. When symptoms of infantile

paralysis appear, the spinal fluid should show the customary signs.

The tests here described are regarded as reliable and confirmatory of clinical signs.

Usual treatment consists of absolute rest in bed, with spinal punctures for release of fluid as may be necessary to relieve intracranial pressure.

The intravenous administration of convalescent poliomyelitis serum (human) in quantities of from 50 to 100 cc is sometimes advocated. There is also antistreptococcus poliomyelitis serum (horse) on the market.

A conclusion drawn from the case cited would be misleading. Was the patient ever in danger? Under some circumstances blood transfusions are beneficial in poliomyelitis as in other infections. Adult blood even in those without a history of infantile paralysis often contains neutralizing substances which are presumably helpful in treating poliomyelitis by transfusion.

### REDUCTION OF GLARE IN OPHTHALMIC LENSES

*To the Editor.*—Kindly inform me whether there is any new type of glass being made for lens purposes which is designed to reduce glare, other than the usual soft light and other tinted lenses. Please omit name.

M.D., Wisconsin

**ANSWER.**—Glare is defined as "a blinding sensation caused by excessive brightness of light in the field of vision, by extreme contrast between a light source and its surroundings or by continued exposure of the eye to a light source" (National Encyclopedia). With that definition in mind it is obvious that all that any glass can do in reducing glare is to reduce the total intensity of light. This is accomplished by the usual tinted lenses, regardless of the trade name, the amount of absorption depending on the depth of the tint. On the other hand, certain supposedly irritating rays of various spectral length can be eliminated by absorption, depending on the character of the glass used. Thus one type of glass will absorb all the ultraviolet rays and, if the glass is thick enough, much of the violet end of the spectrum. In this type fall the Noviol, Hallauer and such. Again, another type will absorb infra-red rays and some of the visible rays at the end of the spectrum, notably the Crookes glass. A third type of very recent origin absorbs a greater percentage of the yellow or sodium waves than any of the other visible rays of the spectrum. This is accomplished by incorporating neodymium in the glass.

### TREATMENT OF SYPHILIS

*To the Editor.*—Would you please advise me what would be considered a satisfactory form of antisyphilitic treatment for the following classes of syphilitic patients: 1. Those with positive blood Wassermann and Kahn reactions in good physical condition. 2. Those with positive Wassermann, Kahn and spinal fluid reactions in good condition. 3. The foregoing in poor physical condition, i.e., those who are undernourished and weak or who have cardiovascular-renal complications. 4. Paucic individuals. 5. Senile patients with syphilis or those over 50 years of age. In each of these categories how long would you consider treatment necessary? (a) provided there is improvement, (b) provided there is no improvement? Would the presence of a psychosis due to syphilis necessarily alter the treatment given? Is aqueous solution of bismuth a satisfactory intermuscular preparation? Please omit name.

M.D., Florida

**ANSWER.**—1. In syphilitic patients with positive blood Wassermann and Kahn reactions, provided they are in good physical condition and show no involvement of the spinal fluid, Cooperative Clinical Group studies have shown that if continuous therapy is employed, alternating courses of neoarsphenamine, ten injections each, and intramuscular injections of a bismuth compound, ten each, for a series of three courses of each, followed perhaps for the next two years by two short courses of intramuscular injections of a bismuth compound a year, will take care of the patient nicely.

2. Syphilitic patients having a positive Wassermann and Kahn test and positive spinal fluid should probably undergo a course of malaria therapy, consisting of from ten to fifteen good chills, provided they stand it all right, after which the preceding therapy might be followed, using continuous, alternating courses of arsenicals and bismuth compounds for at least two years. What should be done after that will depend on the patient's condition and the laboratory examination.

3. Naturally, given a patient in poor physical condition, perhaps having cardiovascular renal complications, the situation is quite different. To be sure, it is difficult to know what is meant by cardiovascular renal complications. If the patient has cardiac syphilis the Cooperative Group, in a report about to be published, has shown that such patients should never have therapy started with an arsenical but should be treated

first with heavy metal for a period of at least three months, and at no time in cardiovascular syphilis should arsenicals in large doses be employed. If one is in any doubt as to the treatment of a patient of this sort, it probably would be well to get the advice of a colleague specializing in this type of work.

4. In dementia paralytica all patients should have a preliminary course of malarial therapy, from twelve to fifteen chills, following which the patients may be treated with alternating courses of arsenicals and bismuth compounds or, if examination of the eyegrounds has been made and the fields are found to be not contracted, it may be possible to use trypanamide, weekly injections being given over a long period. The Cooperative Group advises as much as from thirty to forty injections, provided no eye symptoms intervene. Following this, alternating bismuth and arsenical injections may be used, and, of course, potassium iodide should be employed consistently.

5. One would hesitate to say that a man of 50 years is senile. Many individuals are in vigorous condition at this age, and it might well be that they could receive the same treatment as patients in group 1. If one is dealing with an actual senile case, for example a man of 65 with syphilis, naturally it will be impossible to cure the patient's syphilis, and such an individual should be treated symptomatically, probably with potassium iodide, injections of a bismuth compound or mercury rubs.

In treating parietic patients with a psychosis, malaria should be employed if the patient is in good enough physical condition. Even in an advanced form of the disease, patients sometimes respond in a remarkable manner.

Aqueous solutions of bismuth are of value in cases in which the injections can be given at least twice a week. The great difficulty is that the physician uses an aqueous solution in an injection once a week and feels that he has exhibited enough bismuth to take care of the patient's syphilis. With an aqueous preparation of bismuth it is not possible to raise the level of bismuth in the blood stream to a therapeutic level through a single weekly injection. They must be given twice or three times a week. On that account, in ambulatory patients the physician will usually find it preferable to employ one of the bismuth suspensions; for example, bismuth salicylate or potassium bismuth tartrate. For the student desirous of going further into this problem we would recommend that he consult "The Modern Treatment of Syphilis," by J. Earle Moore, Springfield, Ill., Charles C. Thomas, 1933; "Modern Clinical Syphilology," by John H. Stokes, second edition, Philadelphia, W. B. Saunders Company, 1934, or the publications of the Committee on Research in Syphilis, which have been appearing in the last few years in *Veneral Disease Information*, a publication of the United States Public Health Service.

#### HORMONE TREATMENT IN DELAYED GROWTH

To the Editor:—Is a roentgenogram of one hand and forearm sufficient evidence on which to base the statement that a boy, aged 11 years, has the bone development of a boy of 7 or 8 years? Also is the statement that unless the boy has biweekly injections of 2 cc. of antuitrin (Parke, Davis & Co.) the bones will not grow properly a tenable one? Granted that an 11 year old has the bone development of a boy of 7 or 8 years what, if any, treatment more than proper diet, vitamins, and so on, is indicated? In the case in question there is no clinical evidence of any faulty bone development except that on the roentgenogram. Please omit name.

M.D., New Hampshire.

ANSWER.—In the absence of clinical evidence of faulty bone development in the case in question, it is assumed that the 11 year old boy under discussion is of normal height and weight for his age. There is a lack of information as to clinical observations on mental, sexual and other physical attributes of development. If it is assumed that all other clinical evidence of growth and development in the boy is normal, a roentgenogram of one hand and forearm would not be sufficient evidence for the statement that there had been a retardation in bone development. It is true that roentgen examination is a valuable aid in the study of growth, and a delay in the appearance of centers of ossification may be an index of general retardation in development. The hand has been chosen as the most satisfactory and useful portion of the skeleton to study bone development. In general it may be said that the infant at 1 year of age will show ossification of two or three carpal bones and that all the carpal bones should show centers of ossification at 6 years of age. Thus one may roughly estimate the age of the infant or child by the number of carpal bones ossified and by the degree of ossification. From a roentgenogram of the hand and wrist of an infant or child, one may estimate the approximate age of the individual. However, there is a fairly wide variation within the normal, and if growth and development are otherwise normal, as has been assumed in this case, it is probable that the roentgenographic evidence could be considered within

the lower limits of the normal range. In some conditions in which general growth and development are abnormal, a delay in ossification as shown by roentgenograms of the carpus will have diagnostic significance. Among such conditions may be enumerated congenital or acquired hypothyroidism, rickets and renal rickets, celiac disease, types of dwarfism such as the Lorrain type of infantilism, the ateliosis of Gifford, and the Paltauf type of dwarfism. Treatment in any given case will depend on the cause of the general retardation in development. In a case of delayed ossification due to avitaminosis, such as rickets, the treatment would consist in supplying vitamin D in adequate amounts. In the case of aspecific hormone deficiency, such as hypothyroidism, the administration of thyroid would be indicated.

#### OCCUPATIONAL HAZARDS OF CONCRETE INDUSTRY

To the Editor:—Will you please send me literature on the possible allergic manifestations from concrete and the ingredients of cement, as well as literature on occupational dermatoses that might arise from concrete making?

P. B. BRUMBY, M.D., Lexington, Miss.

ANSWER.—The raw materials of Portland cement vary slightly from plant to plant and from type to type. The basic material is limestone, to which may be added shale, clays, clinkers, silica sand, slag, hydrous aluminum silicate and gypsum. After the mixture has been calcined, the resulting compound is essentially a mixture of calcium silicates. The proportion of free alkali is low, being of the order of 0.2 per cent, but the calcium silicate itself may act as an alkaline irritant. On the addition of water, as in the making of the concrete mixture, the calcium silicates are modified so as to produce more free alkali as calcium hydroxide. It follows that concrete makers are handling a more hazardous material than is true for cement makers. In a cement plant employing about 743 persons, only thirty-seven cases of disabling skin disease of any character took place in a period of three years. Furunculosis was the principal skin disease observed (Thompson and others, "Health of Workers in a Portland Cement Plant," *Pub. Health Bull.* 176, 1928). A true allergic dermatitis following exposure to cement is open to question but has been described by Cohen and Ganot (*Bull. Soc. franç. de dermat. et syph.*, July 1931, p. 1135). Martial states that at least one third of workers handling lime and cement acquire "cementers' itch." Among cement makers a dermatitis has been found in finishers, packers and bag cleaners. Perspiration and other sources of wetness favor the occurrence of skin disorders. In some trades mechanical abrading has to be considered along with the chemical irritation. In addition to the acute dermatitis venenata, a variety of chronic manifestations are recognized, including deep fissures, nail splitting and friability, skin tautness, and ulcers invaded by fungi. The alkali content of cement and of concrete is uniformly accorded chief consideration as the cause of the skin involvement. Additional comment may be found in:

International Labor Office: Occupation and Health, Geneva, 1934.

Anstett, F.: Cementers' Itch, *Bull. Acad. de méd.*, Oct. 20, 1925, p. 902.

#### MULTIPLE IMMUNIZATION

To the Editor:—In the Dec. 28, 1935, issue of THE JOURNAL a question is asked regarding the use of Sauer's whooping cough vaccine. The answer states that active immunizations against pertussis, scarlet fever, diphtheria and smallpox should be separated, each from the others, by intervals of several months in order to prevent one from "conflicting with the other." As each such immunization is specific in nature, I am wondering about the mechanism of such conflict. If these several immunizations were all performed at the same time, or close together, would the immunity subsequently developed against each infection be less as a result of this conflict than if more widely separated? If so, does this same consideration exist when simultaneously immunizing children or adults against smallpox, typhoid fever and cholera?

CARR E. BENTEL, M.D., Medical Corps, U. S. Navy.

ANSWER.—There is no definite proof that concurrent pertussis and diphtheria immunization is undesirable. With between 10 and 15 per cent failures with authorized commercial pertussis vaccine it seems advisable to give the pertussis vaccine a chance, without further complicating matters. When there become available reports of a higher percentage of protection with the commercial vaccine, it would be of interest to try a series of several hundred simultaneous immunizations to determine whether immunity is so influenced. In the present state of our knowledge and experience, it does not seem advisable now to undertake simultaneous injections. Since it is rarely if ever necessary to crowd the various immunization procedures, it seems prudent to allow a sufficient time interval after each to insure the highest degree of immunity response.

## FOOD POISONING

*To the Editor:*—I have been treating a young married woman since July 1935 for a spastic colon. Although the condition was annoying, she was never in acute distress. About the latter part of December she ate a few slices of whole wheat bread and approximately four hours later was seized with violent, generalized abdominal pains accompanied by nausea, vomiting, and later diarrhea. About twelve hours later she appeared to be in a stage of shock with its usual manifestations. It required about a week's care to restore her to her original condition. It was discovered on the same day on which she ate the bread that, although apparently fresh, it contained a greenish, white velvety fungous growth inside the bread measuring about 2 inches long and half an inch wide. There is no doubt that the bread consumed had contained this growth. Kindly give me information concerning this form of food poisoning and any references you may have available. Please do not publish my name.

M.D., Pennsylvania

*ANSWER:*—While within the range of possibility, it is not likely that this was an allergic manifestation. The description is characteristic of acute food poisoning such as has been described for certain strains of staphylococci, of which Jordan and Burrows (*Am. Jour. Hyg.* 20:604 [Nov.] 1934) have recorded nine outbreaks; recently Dack, Bowman and Harger (*THE JOURNAL*, Nov. 16, 1935, p. 1598) described another. It is possible that the green mold was the cause, but unlikely, as other molds, including green ones, growing on bread have not been incriminated as food poisons although probably they are frequently eaten. One must remember, however, that mushrooms are distant cousins of such fungi. It would seem more likely that the food poisoning in this case was caused by some other organism and the most likely explanation, since the disability did not last longer than a week, is that one of the staphylococci was responsible.

## BURNS AND DIABETES

*To the Editor:*—Can you give me any information or references to the literature with regard to burns as a cause of diabetes?

Leo F. Schiff, M.D., Plattsburg, N. Y.

*ANSWER:*—Notwithstanding a considerable study of so-called instances of trauma in relation to the onset of diabetes, no case of burns as a cause of the disease is recalled. It is true that one boy developed diabetes two weeks following a severe sunburn and a physician told the mother that the pancreas was injured by the burn!

Burns as an etiologic factor in diabetes would appear to be unexplainable.

However, a mild diabetes can be made extremely severe by burns. Thus a woman, aged 66, with diabetes of seven years' duration, both of whose legs had been amputated for gangrene, upset a kettle of boiling water over her body while sitting in her wheel chair. She was unable to extricate herself. The following day vomiting began and on the fourth day she entered the hospital in diabetic coma. Although she recovered from the coma, she succumbed to the trauma resulting from the burn and the coma twenty-one days later. Three months before the accident, although her heart was fibrillating during a stay in the hospital, she was sugar free with carbohydrate 145 Gm., protein 50 Gm. and fat 76 Gm., and the fasting blood sugar was 170 mg. per hundred cubic centimeters without insulin.

## FACTORS AFFECTING VIABILITY OF SPERM

*To the Editor:*—In the paper on natural conception control by Dr. Latz in *THE JOURNAL*, Oct. 19, 1935, he discusses factors governing the periodicity in the fertility and sterility of women in part as follows (p. 1241): "1. The life of the sperm cell within the female genitalia is less than forty-eight hours. The most important factor influencing the length of the fertility of the spermatozoa in a harmful way is the body temperature within the vagina. The scrotum serves as a refrigerating apparatus for the testicles, keeping the spermatozoa at a temperature which is several degrees lower than that of the circulating blood." To one who is interested in the subject of fertility and sterility in animals, the question arises as to what effect, if any, the seminal vesicles may have in offsetting the so-called refrigerating action of the scrotum. So far as the lower animals are concerned, most of them have seminal vesicles which, it is understood, act as reservoirs for the collection of spermatozoa and spermatic fluid. From the location of the vesicles within the abdominal cavity, it would seem that the spermatozoa are there subjected to temperatures equal to those which would obtain in the vagina. If this is true and if the viability of the spermatozoa is affected adversely by such high temperatures, what may be said about the effect of the latter on the germ cells while they are in the seminal vesicles? Please omit name.

V.M.D., New Jersey.

*ANSWER:*—In answering the question as to the effect of the temperature in the vesicle or vagina on the spermatozoa it must be understood that, although a temperature a few degrees lower than the body may be necessary for spermatogenesis or the production of spermatozoa, the mature sperm cells can and do live at body temperatures that exist in the vagina or the

vesicles. The longer life of spermatozoa in the vesicle as compared with their short life in the vagina is due to more than one factor; in the first place the vesicle produces a secretion that activates or feeds the spermatozoa (this secretion is naturally absent in the vagina) and, secondly, the high bacterial content and often the acid reaction of the vagina are adverse factors for the life of the sperm cells.

## WASHING PERITONEAL CAVITY

*To the Editor:*—Bevan (*S. Clin. North America* 15:681 [June] 1935) advises in peritonitis the washing out of the general peritoneal cavity with physiologic solution of sodium chloride. Is there general agreement on the point that irrigation is advisable? I refer to the conception that irrigation removes plastic exudate and thus allows increased absorption of toxins by the peritoneum. Please discuss.

M.D., Pennsylvania.

*ANSWER:*—There is no general agreement on the point that irrigation of the peritoneal cavity in general peritonitis is advisable. There does seem to be agreement that there is value in removing fluids from the abdomen within the six hours subsequent to perforation, penetration or rupture of a hollow abdominal viscus. This can best be done by means of a suction apparatus. There is no objection to washing out the general peritoneal cavity during an operative procedure in which local contamination has occurred.

## DEODORIZED KEROSENE

*To the Editor:*—In *THE JOURNAL*, Nov. 2, 1935, p. 1455 in *Queries and Minor Notes*, deodorized kerosene was suggested in the treatment of scalp conditions. I have inquired at several places but no one seems to know where I can buy deodorized kerosene. I would appreciate it greatly if you could tell me where such a product is sold. Please omit name.

M.D., Massachusetts.

*ANSWER:*—The Welty Company, 337 Sigel Street, Chicago, markets deodorized kerosene. It has only a slight kerosene odor and is said to be much less inflammable than ordinary kerosene. Besides its skin stimulating qualities it is a cleansing agent, dissolving greases, waxes and resins. It also is a solvent of camphor, iodine, menthol, thymol and other substances.

## PAINFUL TONGUE

*To the Editor:*—A white woman, aged 68, has been complaining of a painful tongue for the past year. The majority of her foods seem peppery. The pain is intense, although there are occasional periods of remission. The surface of the tongue is smooth and red. There are no visible ulcerations. Her blood pressure is 240 systolic, 120 diastolic; red blood cells 2,750,000; hemoglobin 65 (Sahli); smear is normal; the urine shows albumin +++ with hyaline and granular casts. I have been treating her for the hypertension and anemia. Kindly advise as to treatment for sore tongue. Please omit name.

M.D., New York.

*ANSWER:*—A smooth, painful, red tongue in an elderly female associated with a hyperchromic anemia and a 1.5 color index is frequently seen in pernicious anemia.

Complete and careful blood studies should be performed. In addition, blood chemistry studies including nonprotein nitrogen, sugar, creatinine and serum proteins should be done. If the proteins are low, adequate intake should be provided. In addition, liver, either orally or parenterally, may be given. Diluted hydrochloric acid after meals may also be of value.

## ANTIEMETIC COMBINATION

*To the Editor:*—Zahorsky in his "Synopsis of Pediatrics" speaks at length of the use of milk of magnesia and a minute amount of phenol as an antiemetic. Could you kindly advise the exact amount of each substance? Please omit name.

M.D., Illinois.

*ANSWER:*—The addition of as small a quantity as 0.05 Gm. of phenol to a teaspoonful or tablespoonful dose of magnesia magma would constitute a suitable antiemetic combination.

## DOSAGE OF CHLORAL IN ECLAMPSIA

*To the Editor:*—In the 1935 supplement of volume XVIII of *Sajous' Cyclopedia of Medicine*, page 570, appears the following about eclampsia: "Patients who are very restless should be given chloral hydrate 20 Gm. (5 drachms) and sodium bromide 60 Gm. (2 ounces) by rectum." I never thought it was possible to give such a heavy dose of chloral and bromide. In my other medical books the largest dose prescribed in such cases is: chloral hydrate 4 Gm. (1 drachm) and sodium or potassium bromide 8 Gm., or 2 drachms.

OVILA BRIS, M.D., Coaticook, Que.

*ANSWER:*—There is an obvious error in this statement, as from 6 to 12 Gm. of chloral hydrate has produced death. The doses quoted as "largest doses" should be accepted as such.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

ALASKA: Juneau, Sept. 1. Sec., Dr. W. W. Council, Juneau.  
ARIZONA: Phoenix, July 7-8. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: *Basic Science*. Little Rock, Nov. 2. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. *Medical (Regular)*. Little Rock, Nov. 10. Sec., Dr. A. S. Buchanan, Prescott. *Medical (Eclectic)*. Little Rock, Nov. 10. Sec., Dr. Clarence H. Young, 207½ Main St., Little Rock.

CALIFORNIA: San Francisco, July 6-9, and Los Angeles, July 20-23. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, July 7. Sec., Dr. Haivey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT: *Medical (Regular)*. Hartford, July 14-15. *Endorsement*. Hartford, July 28. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Medical (Homoeopathic)*. Derby, July 14. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Dover, July 14-16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: Washington, July 13-14. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

HAWAII: Honolulu, July 13-16. Sec., Dr. James A. Morgan, 48 Alexander Young Bldg., Honolulu.

IDAHO: Boise, Oct. 6. Commissioner of Law Enforcement, Hon. Emmitt Post, 205 State House, Boise.

IOWA: *Basic Science*. Des Moines, July 14. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.

MAINE: Augusta, July 7-8. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, July 14-16. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MONTANA: Helena, Oct. 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

NEW HAMPSHIRE: Concord, Sept. 10-11. Sec., Board of Registration in Medicine, Dr. Charles Duncan, State House, Concord.

NEW MEXICO: Santa Fe, Oct. 12-13. Sec., Dr. Le Grand Ward, Santa Fe.

NORTH DAKOTA: Grand Forks, July 7-10. Sec., Dr. G. M. Williamson, 4½ S. 3d St., Grand Forks.

OREGON: *Basic Science*. Corvallis, July 18. Sec., Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 7-11. Sec., Board of Medical Education and Licensure, Mr. Clarence E. Ackley, 400 Education Bldg., Harrisburg.

PUERTO RICO: San Juan, Sept. 1. Sec., Dr. O. Costa Mandry, Box 536, San Juan.

RHODE ISLAND: Providence, July 2-3. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Rapid City, July 21-22. Dir., Division of Medical Licensure, Dr. Park B. Jenkins, Pierre.

UTAH: Salt Lake City, July 10. Dir., Department of Registration, Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.

WASHINGTON: *Basic Science*. Seattle, July 9-10. *Medical*. Seattle, July 13-15. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.

WEST VIRGINIA: Bluefield, July 13. State Health Commissioner, Dr. Arthur E. McClue, Charleston.

WISCONSIN: Milwaukee, June 30-July 3. Sec., Dr. Robert E. Flynn, 401 Main St., La Crosse.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS. *Parts I and II*. Sept. 14-16. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examination and review of case histories of Group B candidates will be held in various cities in the United States and Canada, Nov. 7. *Applications must be filed at least sixty days prior to the examination.* Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: New York, Sept. 26. *All applications and case reports must be filed sixty days before date of examination.* Address, 122 So. Michigan Ave., Chicago.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Cleveland, Jan. 9. Sec., Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: New York, Sept. 25-26. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Baltimore and Cincinnati in November. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 29-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Cleveland, Sept. 25-27. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester, Minn.

### California Reciprocity and Endorsement Report

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports 30 physicians licensed by reciprocity and 3 physicians licensed by endorsement from Feb. 6 through April 2, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of California Medical School.....	(1934)		Washington
University of Colorado School of Medicine.....	(1934)		Colorado
American Medical Missionary College, Chicago.....	(1900)		Mass.
Loyola University School of Medicine.....	(1933)		Illinois
Northwestern University Medical School.....	(1929)		Ohio

University of Illinois College of Medicine.....	(1918), (1920)	Illinois
State University of Iowa College of Medicine.....	(1933)	Iowa
Tulane University of Louisiana School of Medicine.....	(1934)	Louisiana
Baltimore Medical College.....	(1909)	New York
Johns Hopkins University School of Medicine.....	(1906), (1933)	Maryland,
(1926) Minnesota		
Harvard University Medical School.....	(1928)	Wisconsin
Detroit College of Medicine.....	(1907)	Michigan
University of Minnesota Medical School.....	(1929), (1932)	Minnesota

Medico-Chirurgical College of Philadelphia.....	(1916)	U. S. Army
Woman's Medical College of Pennsylvania.....	(1921)	N. B. M. Ex.

### Alabama Reciprocity and Endorsement Report

Dr. J. N. Baker, secretary, Alabama State Board of Medical Examiners, reports 15 physicians licensed by reciprocity and 1 physician licensed by endorsement from Jan. 13 through April 20, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Howard University College of Medicine.....	(1932)		Georgia
Emory University School of Medicine.....	(1933), (1934)		Georgia
Tulane Univ. of Louisiana School of Med.....	(1931), (1934)		Louisiana
University of Michigan Medical School.....	(1931)		Michigan
Washington University School of Medicine.....	(1930)		Missouri
Temple University School of Medicine.....	(1932)		S. Carolina
Memphis Hospital Medical College.....	(1904)		Tennessee
Univ. of Tennessee College of Medicine..	(1933, 2), (1934, 2)		Tennessee
Vanderbilt University School of Medicine....	(1928), (1934)		Tennessee

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad. of
Columbia Univ. College of Physicians and Surgeons..	(1933)	N. B. M. Ex.

### South Dakota January Report

Dr. Park B. Jenkins, director, Division of Medical Licensure, reports the written and practical examination held in Pierre, Jan. 21-22, 1936. The examination covered 14 subjects and included 105 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. Three physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Boston University School of Medicine.....	(1934)		87
University of Minnesota Medical School.....	(1935)		84
St. Louis University School of Medicine.....	(1927)		85

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Georgetown University School of Medicine.....	(1924)		Ohio
Northwestern University Medical School.....	(1924)		Michigan
University of Tennessee College of Medicine.....	(1934)		Tennessee

### Rhode Island January Examination

Mr. Robert D. Wholey, chief, Division of Examiners, reports the oral, written and practical examination held at Providence, Jan. 2-3, 1936. The examination covered 20 subjects and included 50 questions. An average of 80 per cent was required to pass. Four candidates were examined, 3 of whom passed and 1 failed. Two physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Harvard University Medical School.....	(1932)		88.9
Tufts College Medical School.....	(1934)		80
Hahnemann Med. College and Hospital of Philadelphia.	(1935)		85.4

School	FAILED	Year Grad.	Per Cent
Laval University Faculty of Medicine.....	(1934)		40

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad. of
Harvard University Medical School.....	(1932, 2)	N. B. M. Ex.

## Book Notices

**Lobar Pneumonia and Serum Therapy, with Special Reference to the Massachusetts Pneumonia Study.** By Frederick T. Lord, M.D., Member of the Board of Consultation, Massachusetts General Hospital, and Roderick Heffron, M.D., Field Director, Pneumonia Study and Service, Massachusetts Department of Public Health. Cloth. Price, \$1. Pp. 91, with 11 illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1936.

The authors of this manual have placed physicians and students in their debt by a succinct presentation of the elements of serum therapy for lobar pneumonia due to pneumococcus types I and II. They provide evidence of the success of serum therapy based on a study of more than 900 patients who were treated by 400 physicians. They are correct in stating that specific treatment in the hands of general practitioners presents a community problem because of the need for prompt typing and the provision of serum for those unable to afford it. The chapters cover the application of specific therapy to lobar pneumonia, etiology, factors influencing recovery, clinical diagnosis and selection of cases, the recognition of the pneumococcus type, antipneumococcus serum, administration of serum and dosage, serum reactions and their treatment, and the results of serum treatment. The procedures recommended are sound. The importance of studying cultures of the heart's blood or the brain of sputum-injected mice is not mentioned, though in some instances they are the first source of knowledge of the type. No method of gaging the adequacy of the dose of serum before clinical improvement or when invasion by an additional organism has occurred is described, though two are available: the presence of agglutinins in the patient's blood and the Francis test or the skin reaction to the specific carbohydrate. There are, as there must be in a subject that is developing, many points in which more experience will bring modification of opinion and practice. Warming serum above hand temperature may be a source of difficulty and should not be recommended.

**Lésions du pancréas et troubles fonctionnels pancréatiques: Diagnostic en clinique par l'épreuve à la sécrétine purifiée.** Par Marc Bolgert. Préface du Professeur G. Roussy. Paper. Price, 45 francs. Pp. 225, with 22 illustrations. Paris: Masson & Cie, 1935.

In this monograph Bolgert, working in the clinic of Professor Chiray and in the laboratory of Professor Roussy, reports the effect produced on the secretion of the pancreatic juice by the intravenous injection of purified secretin. After bile samples A, B and C have been secured according to the recognized Meltzer-Lyon technic, secretin is given. Trypsin and lipase are then determined in the clear secretion of the pancreatic juice. Eighty cases of various types of pancreatic disease were studied by this method and the results are presented. There are excellent illustrations of disease of the pancreas found in association with the cases under investigation. Thus, figure 15 is an illustration of a pancreas filled with calcified granules and in this case the volume of the juice after the secretin injection as well as the lipase and trypsin were reduced. A discussion of similar cases in the literature is included. In Bolgert's patient the fasting blood sugar was normal but subsequently advanced to a mild diabetic level. Following the injection of secretin the pancreatic response is immediate or occurs after a few minutes' delay. Fluid is collected from the duodenal tube every five or ten minutes and the volume noted. Its content in lipase and trypsin is determined. The secretion lasts for about twenty-five minutes but can be prolonged. It is then often mixed with gastric juice. Methods of the determination of lipase and trypsin are recorded. In normal cases the pancreatic response is immediate, and the volume of the juice excreted is much increased, reaching from 100 to 150 cc. in fifteen or twenty minutes and the lipase and trypsin are more than doubled after the injection. In abnormal cases the pancreatic response is delayed and there is a diminution of the quantity of the enzymes. Generally if there is a change in one ferment the other follows suit. In part I the book presents a comprehensive study of pancreatic symptomatology based on clinical, x-ray and pathologic methods. In part II the action of secretin, the technic of administration, the results of the test and its interpretation are described, and in part III func-

tional pancreatic disturbances as found in the course of various diseases of the pancreas, liver and gallbladder, and other states are touched on. It would appear that this monograph advances definitely the opportunity for learning the functional changes that are taking place in the pancreas and opens up methods that can be tried generally in the clinic to solve the diagnosis of conditions of a gland hitherto always difficult to investigate.

**A Guide to Psychiatric Nursing.** By F. A. Carmichael, M.D., Superintendent, Osawatomi State Hospital, Osawatomi, Kansas, and John Chapman, M.A. Second edition. Cloth. Price, \$2.25. Pp. 175, with 31 illustrations. Philadelphia: Lea & Febiger, 1936.

It is at once apparent that this book is the result of mature judgment. It had its inception in a course of lectures for the nurses in the Osawatomi State Hospital. The present edition is well written and the illustrations are excellent. It is intended especially for training the psychiatric nurse, which purpose it should serve with credit. The book is well arranged. The introductory chapter is on the history of psychiatry and it takes the student in an orderly manner through the various developmental stages of mental history. The chapter on definitions of mental disease is rather short and might better have been incorporated in one of the following chapters. The classification of mental diseases employed by the authors is one modified from that of Henderson and Gillespie. There is a short but excellent chapter on psychopathology which, however, may be a little difficult for the average student nurse to comprehend. The same may be said of the chapter on the etiology of mental disease. Chapter 10, which is given over to the symptomatology of mental disease, contains many practical bits of information for the nurse and, as the authors suggest, what they wish "to impress on nurses is the value of accurate and detailed observation." It is rather surprising that no more space is given to the discussion of encephalitis, mental deficiency, and some of the psychoneuroses, especially neurasthenia. The sane handling of patients is emphasized. As is stated in the preface, "above all, we stress the point that these unfortunates who have been committed to our care are human, neither wild beasts in some instances nor beasts of burden in others." Appendix A, which deals with hereditary factors in mental defects and disease, while appropriate, might just as well have been included in the chapter on etiology of mental diseases. Appendix B, which deals with a proposed modification of the present classification of mental diseases, seems a little profound for the average student nurse but might be referred to in the chapter on the classification of mental diseases. The book represents a new and refreshing method of presentation of its material. It contains many good references for collateral reading and, all in all, should be of considerable help in the teaching of psychiatry to nurses.

**Geopsyché: Die Menschenseele unterm Einfluss von Wetter und Klima, Boden und Landschaft.** Von Dr. Dr. Willy Hellpach, Professor an der Universität Heidelberg. Fourth edition of "Geopsychische Erscheinungen." Cloth. Price, 9.50 marks. Pp. 317. Leipzig: Wilhelm Engelmann, 1935.

The fact that Hellpach's book "Geopsyché" (the 1923 edition was published under the title of *Geopsychische Erscheinungen*) has reached a fourth edition must indicate a growing continental interest in the study of man as a creature of his environment; an interest in the patient as diseased because of maladjustment to the world about him. But Hellpach is not an environmentalist in the sense of the psychologist. For him, environment is the universe—more particularly the "airs, waters, places" on which Hippocrates built his structure. In the English speaking countries this point of view is still medically remote, though in the collateral sciences, in general biology, in zoology, in botany, a broader concept is forging ahead, if Livingston's evaluation is correct. This edition has been almost entirely rewritten and the material has been carefully selected, condensed and amplified. As it now stands it presents an excellent review of the interrelation of the environment and the psychic phenomena. Fundamentally Hellpach's interests relate to the effects of climate, in contradistinction to the immediate meteorological effects that are experienced as weather change, though even here the treatment is adequate. Diurnal rhythm, seasonal rhythm, the rhythm of the lunar cycle are all discussed, as are the effects of local geographic and geological differences. A whole section is devoted to the psychic effects of the landscape

on the individual and on the racial group. The psychologist and the psychiatrist interested in the wider aspect of his subject is presumably familiar with the previous editions; for the younger German reading members of these groups the new edition should prove interesting as well as useful.

**The Art of Ministering to the Sick.** By Richard C. Cabot, M.D., and Russell L. Dicks, B.D. Cloth. Price, \$3. Pp. 384. New York: Macmillan Company, 1936.

Dr. Richard Cabot has been for many years a leading clinician and teacher of scientific medicine. He has also been an eloquent exponent of the social side of medicine and the human side of illness. His books on *Physical Diagnosis and Facts on the Heart* have companion volumes in *What Men Live By* and *Social Service and the Art of Healing*. In this work he has as co-author a minister of the gospel. The theme that is developed is that in time of painful or incapacitating illness, even when the patient is knowingly rapidly approaching death, there is something more to be done than to try to work a cure or alleviate physical suffering. Encouragement and psychic therapy are helpful but may not go far enough. Religion has a place. Its comfort may be brought not only to the orthodox believer but to the backslider, the doubter, the agnostic or the frank disbeliever. This religion need not be, nor should it be, narrowly sectarian. Rightly handled it is helpful in restoring mental poise and happiness; it may have a wholesome effect on the physical ailment. This is the belief of the authors based on a rich experience, of which they give illustrative examples. Those who are interested in these features of medical practice—and all should be—will find here much food for thought and many helpful suggestions. The authors ask for specific criticism of certain views that they hold—some tentatively, perhaps. In a brief book notice it is hardly in place to express opinions, much less to advance arguments pro or con. The authors will no doubt welcome such criticism as helpful. It is to be hoped that many readers will offer this frankly asked for comment.

**Alimentación y dietética.** Por el Dr. Marlo Scheitngart, docente libre de patología médica de la Facultad de medicina de Buenos Aires. Paper. Pp. 583, with one illustration. Buenos Aires: Aniceto Lopez, 1935.

This appears to be a useful textbook on dietetics, containing as it does a good deal of information not only as to the more technical aspects of dietetics but also as to the more practical ones. The first chapters are on calorimetry, basal metabolism and the constitution and caloric values of the several foods. Then there are chapters on the feeding of children, pregnant women and the aged. Three chapters are devoted to a discussion of the problems of feeding as they apply particularly to Argentina. In the final third of the book the author gives practical details of the dietetic treatment of the several diseases in which dieting is most effective. In the last two chapters Scheitngart gives some advice about the preparation of foods for the sick, together with a number of recipes. The book can be recommended to physicians who read Spanish.

**La litiasis reno-ureteral bilateral.** (Estudio clínico e indicaciones en su tratamiento). Por el Dr. Pedro Cifuentes, cirujano-urólogo y decano-jefe del Hospital de la Beneficencia General. Paper. Pp. 83, with illustrations. Madrid: Grafica Universal, 1935.

Dr. Cifuentes has studied ninety-seven cases of reno-ureteral lithiasis in which operation was performed. The cases are carefully charted according to history, treatment and results. Some excellent plates are included as well as a fairly comprehensive bibliography. It is stated that the average incidence of bilateral renal lithiasis is 21 per cent, which seems to be an average figure, judging from the divergence of reports that may be found in the literature. When speaking of bilateral lithiasis, the author differentiates between medical and surgical bilateral lithiasis. The problem of medical bilateral lithiasis seems to have been discussed in other papers and is not treated in this work. His concept of bilateral lithiasis includes (1) renal lithiasis with surgical indications on both sides, (2) surgical stones on one side and stones with medical indications on the other, and (3) surgical lithiasis in one side with medical or surgical lithiasis ultimately appearing in the other kidney. The frequent association of bilateral lithiasis with urinary infection is noted, and this is considered one of the etiologic factors, as well as the influence of diathesis, alkalis, nutrition and

osteomalacia. Emphasis is placed on the importance of complete roentgen examination, including pyelograms and retrograde, intravenous and pneumoradiography before the operation is undertaken. The author recommends that the kidney with the best function be operated on first, thereby minimizing shock and restoring as much function as possible before the kidney with more serious involvement is treated. The cases have been carefully worked out and the author has presented his material convincingly.

**How the President, Thomas Jefferson, and Doctor Benjamin Waterhouse Established Vaccination as a Public Health Procedure.** By Robert H. Halsey, M.D. Presented Before the Section of Historical and Cultural Medicine, New York Academy of Medicine, March 14, 1934. History of Medicine Series, No. 5, Issued under the Auspices of the Library of the New York Academy of Medicine. Paper. Price, \$1. Pp. 58, with 3 illustrations. New York: The Author, 1936.

Historians in the field of medicine know that Dr. Benjamin Waterhouse was probably chiefly concerned with the introduction of smallpox vaccination into the United States. Few, however, have stopped to realize how significant was his experiment or the extent to which it concerned the nation as a whole. Dr. Robert Halsey has collected from many sources the details of this incident and he presents the story with numerous quotations of letters and papers, which give a good understanding of the situation. Few people realize the extent to which Thomas Jefferson was interested in these experiments and how significant was his influence in aiding the introduction of vaccination into this country. Without his help many years might have elapsed before it was recognized as an established public health measure.

**An Epitome of the Laboratory Diagnosis and Treatment of Tropical Diseases.** By Horace M. Shelley, F.R.F.P.S., M.R.C.S., L.R.C.P., Government Pathologist, Nyasaland, East Africa. Cloth. Price, 2s. 6d. Pp. 81. London: John Bale, Sons & Danielsson, Ltd., 1936.

This small pocket manual is too elementary and incomplete to assist the experienced physician in actual practice, and too indefinite and brief to assist the inexperienced physician. It omits much recent work in the field of its title; e. g., in the insufficient and poorly balanced discussion of the treatment of amebiasis, malaria, roundworms and sprue. The illustrations are of doubtful value as diagnostic aids. Dangers of drug toxicity are not evaluated; e. g., in the recommendation of emetine dosage and of acetarsone (stovarsol). The two short paragraphs on heat stroke are completely archaic. Careless and vague statements are found, as on page 22, where in the treatment of blackwater fever it is urged that the patient "be kept absolutely quiet in bed in a dorsal decubitus," . . . and "he should therefore perform his excretory functions in the prone position." Enough has been noted to show that the booklet is not satisfactory for the purpose designed in the title.

**Diet Manual of University Hospital, University of Michigan.** Prepared by the Department of Dietetics, University Hospital. Second edition. Cloth. Price, \$1. Pp. 85. Ann Arbor: George Wahr, 1935.

The material in this manual is approved by the Department of Medicine, Surgery and Pediatrics of the University of Michigan Hospital. It lists the routine diets, special modifications such as diabetic, ketogenic, low and high caloric diets, modifications of fibers, allergic diets, test meals and the special procedures used in pediatrics. The book is small, compact and useful.

**Endocrine Tumours, and Other Essays.** By Frederick Parkes Weber, M.A., M.D., F.R.C.P., Senior Physician to the German Hospital, London. Cloth. Price, 7s. 6d. Pp. 207. London: H. K. Lewis & Co., Ltd., 1936.

Any one interested in endocrine tumors should not be misled by the title, for a discussion of this subject occupies but thirty pages in the book and contains nothing new or worth while. A good idea of the character of the rest of the book may be gained from the subjects of a few of the essays: "change of air in young adult life and early middle age," "billiousness and bilious attacks, especially those induced in some persons by sea air," "regarding the 'stuff' of which dreams are made—the psychophysiologic basis of dreams." The author's style makes the book almost unreadable, there being but few pages that do not contain many parenthetical remarks. The essays are of no general interest. This book should have been distributed privately to the author's sympathetic friends.

**Those Were Good Days!** By Carl Ludwig Schleich. Translated by Bernard Miall. Cloth. Price, \$3.50. Pp. 280, with 9 illustrations. New York: W. W. Norton & Company, 1936.

Dr. Schleich is known primarily for his contribution to local anesthesia. More than 365,000 copies of his autobiography have been sold in the German edition. He writes with a fine sense of humor, and his story is especially interesting because it is a record of the days when German medical science meant much to all the world. It was a time without the sadness, the agitation of the revolution characteristic of German medicine today. In all those who loved the old Germany this book will evoke a sad nostalgia. Especially interesting are the pages devoted to the work of Paul Ehrlich as Schleich saw him.

**Pathologie digestive.** Par P. Harvier, professeur à la Faculté de médecine de Paris. Collection des Initiations médicales, publiée sous la direction du Dr A. Sézary. Paper. Price, 22 francs. Pp. 162, with 16 illustrations. Paris: Masson & Cie, 1935.

This is a primer for the student of gastro-enterology. The author discusses the subject in four chapters including motor, secretory and sensory disturbances and methods of examination. Emphasis is laid on the fact that all digestive disturbances are interrelated, and the divisions made are schematic for purposes of study. The more common disturbances are briefly but clearly treated, and illustrations are used to emphasize the more important diseases. The more complicated diseases are discussed briefly. The volume is easily read and should be of decided benefit to the young student.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts: Silicosis Not an Occupational Disease.**—The workman, Pero, was employed as an attendant on a rock-crushing machine. During the course of his employment, he contracted silicosis and was awarded compensation for several months. About three years later, claiming that he was suffering from permanent partial or total disability, he instituted proceedings for further compensation and the district court entered judgment in his favor. The state treasurer, representing the state compensation fund, appealed to the Supreme Court of Wyoming.

The Wyoming workmen's compensation act provides, in part:

The words "injury and personal injury" shall not include injury caused by the wilful act of a third person directed against an employee for reasons personal to such employee, or because of his employment; nor a disease, except, as it shall directly result from an injury incurred in the employment.

It was contended that the workman was suffering from an occupational disease and that such a disease is not compensable under the Wyoming act. But, said the court, the workman in this case was not suffering from an occupational disease, as defined in *Victory Sparkler & Specialty Company v. Franks*, 147 Md. 368, 128 A. 635:

An occupation or industry disease is one which arises from causes incident to the profession or labor of the party's occupation or calling. It has its origin in the inherent nature or mode of work of the profession or industry, and it is the usual result or concomitant. If, therefore, a disease is not a customary or natural result of the profession or industry, per se, but is the consequence of some extrinsic condition or independent agency, the disease or injury cannot be imputed to the occupation or industry, and is in no accurate sense an occupation or industry disease.

In the present case, continued the Supreme Court, neither the workman nor his employer regarded the inhalation of the rock dust emanating from the crusher as dangerous. No precautions were taken to protect the workman against such an injury as occurred. No one suggested to him the need for any protection. It was by chance that he was stationed for his work in such a position that the prevailing air currents during the period of his employment blew the dust clouds constantly on

him. The exact date could be determined when he began to spit up blood as a consequence of the continued inhalation and cutting of sharp rock particles in his lungs. The time when the true character of his injury was discernible was equally determinable. There was, the court said, not a scintilla of evidence indicating that the injury suffered by the workman was the customary and natural result of the work in which he was engaged, nor was there any evidence that it was the usual result to be expected in working as he did during the period he was employed. There was no proof that any other workman, working under like conditions, ever suffered as did Pero. The record in the case, the court said, would not support a holding that the injury in question was an occupational disease. Whether the abnormal condition produced in the workman's lungs in consequence of the inhalation of the particles of rock dust is regarded as a disease or as a mechanical hurt, growing progressively worse, on account of the sharp particles retained in the lungs, it "directly" resulted, the court concluded, "from an injury incurred in the employment."

The award of compensation was therefore affirmed.—*In re Pero: Pero v. Collier-Latimer, Inc. (Wyo.)*, 52 P. (2d) 690.

**Optometry Practice Acts: Sufficiency of Notice of Revocation Proceedings.**—The West Virginia optometry practice act authorizes the board of optometry to revoke the license of a licentiate for "advertising, practicing, or attempting to practice under a name other than one's own." It further provides that in revocation proceedings "a statement of the charges against the holder thereof and a notice of the time and place of hearing shall be served upon such person." The board instituted revocation proceedings against Eddy and served a notice on him, containing the following:

You are hereby notified that the charges against you are that you are operating in violation of law; that you are operating through the Kay Jewelry, a corporation; that you have received from and are receiving from the Kay Jewelry a salary, purporting said salary to be a percentage of the payments made by certain customers whose names will be furnished to you upon request.

On receipt of this notice, Eddy instituted original proceedings in the Supreme Court of Appeals of West Virginia to restrain the board from proceeding further against him, contending that the notice served on him failed either to charge the violation of any law of the state or to set out any of the statutory grounds for which a license may be revoked.

The Supreme Court of Appeals was of the opinion, however, that the notice was sufficient fairly to inform Eddy of the nature of the misconduct for which it was proposed to revoke his license. He was advised by the notice that he was "operating in violation of law," and the particulars wherein he had violated the law were set out. The notice, in the opinion of the court, indicated on its face that the board accused Eddy of doing one of the acts which the optometry practice act made a cause for revocation; namely, "advertising, practicing, or attempting to practice under a name other than one's own." Furthermore, said the court, the legislature may constitutionally confer authority on the board of optometry to suspend or revoke a license.

The Supreme Court of Appeals accordingly denied Eddy the relief he sought.—*Eddy v. West Virginia Board of Optometry (W. Va.)*, 182 S. E. 870.

## Society Proceedings

### COMING MEETINGS

- American Physiotherapy Association, Los Angeles, June 28-July 2. Miss Jefferson I. Brown, Tichenor Hospital School, Long Beach, Calif., Secretary.
- Montana Medical Association of Billings, July 8-9. Dr. E. G. Balsam, 208½ North Broadway, Billings, Secretary.
- National Medical Association, Philadelphia, Aug. 16-22. Dr. W. Harry Barnes, 1315 North 15th St., Philadelphia, Acting Secretary.
- Pacific Northwest Medical Association, Portland, Ore., July 8-11. Dr. C. W. Countryman, 407 Riverside Avenue, Spokane, Wash., Executive Secretary.
- Wyoming State Medical Society, Cody, Aug. 24-25. Dr. Earl Whedon, 50 North Main Street, Sheridan, Secretary.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

#### Alabama Medical Association Journal, Montgomery

5: 337-372 (April) 1936

Oxygen Therapy in General Practice. M. E. Smith, America.—p. 337.  
Some Moot Questions in Obstetrics. H. P. Hewitt, Chattanooga, Tenn.—p. 340.

\*Treatment of Secondary Muscular Disturbances with Aminoacetic Acid: Preliminary Report. S. R. Terhune and A. H. Green, Birmingham.—p. 343.

Pain and Its Relief. O. R. Grimes, Gadsden.—p. 346.

Alabama's Eighty-Nine Years of Medical Organization: Brief History of the Association. D. L. Cannon, Montgomery.—p. 348.

Eye Diseases of Interest to the General Practitioner. D. Burkhead, Opelika.—p. 356.

**Treatment of Muscular Disturbances with Aminoacetic Acid.**—Terhune and Green became interested in muscular disturbances secondary to primary disease conditions because so many patients were referred for orthopedic consultation. Up to the present time they have used aminoacetic acid in five such cases, which are reported. The patients' chief complaints were chronic fatigue and easy fatigability. Aminoacetic acid was given in doses of from 30 to 45 Gm. a day. There was great improvement in each patient. The conclusions are that: 1. Aminoacetic acid is most likely of value in cases of primary muscle disturbances. 2. There may exist a syndrome of secondary muscular disturbances in disorders with different clinical aspects. 3. Secondary disturbances in muscle metabolism are ameliorated by the administration of aminoacetic acid. 4. The influence of aminoacetic acid therapy is probably solely confined to muscle metabolism.

#### American Journal of Diseases of Children, Chicago

51: 765-1006 (April) 1936

\*Blood Picture After Splenectomy in Children, with Especial Reference to Platelets. Martha Wollstein and Katherine V. Kreidel, New York.—p. 765.

Values for Red Blood Cells of Average Infants and Children. E. R. Mager and Marjory I. Andresen, Denver.—p. 775.

\*Rapid Typing of Pneumococci by Neufeld Reaction Directly from Laryngeal Swabs from Infants and Children. Julia Vinograd, Rosa Lee Nemir and W. H. Park, New York.—p. 792.

Metabolism of Adolescent Girls: I. Basal Metabolism and Energy Exchange. C. C. Wang, Mildred Kaucher and Mary Wing, Cincinnati.—p. 801.

Infantile Tetany: Metabolic Study. J. B. Pincus and I. F. Gittleman, Brooklyn.—p. 816.

Respiration in Infancy: II. Study of Rate, Volume and Character of Respiration in Healthy Infants During Neonatal Period. Jean Deming, San Francisco, and J. P. Hanner, Atlanta, Ga.—p. 823.

**Blood Picture After Splenectomy in Children.**—Wollstein and Kreidel performed splenectomy in forty-four children for traumatic rupture in three, rheumatic disease in twenty, splenomegaly of undetermined origin in one, congenital hemolytic icterus in four, Cooley's anemia in eight and hemorrhagic thrombocytopenia in eight. The ages of the children ranged from 11 months to 12 years and 11 months. When there had been no preoperative diminution in the number of platelets, as in cases of traumatic rupture, rheumatic disease and congenital hemolytic icterus, there was no immediate increase after the operation; but an increase appeared toward the middle or end of the first week, rarely before the third day. In cases of hemorrhagic thrombocytopenia, in which the number of platelets had been much diminished, splenectomy was followed by an immediate rise in all but one instance. This rise was not maintained in a fatal case and was delayed in the case of a boy who has lived two and one-half years after operation. The peak was reached, as a rule, in the second postoperative week, and a level of 1,000,000 platelets per cubic millimeter

was maintained for a week or for several months. A fall in the reticulocyte count was characteristic of typical cases of congenital hemolytic icterus. In patients with Cooley's anemia, the response of the platelets was most irregular in onset, number and duration of the increase, and it was never as high or of as long duration as in the other groups. Increase in the number of nucleated red cells is characteristic in these cases. Operations other than splenectomy were not followed by any appreciable rise in the platelet count during the postoperative period of observation. None of the four control children showed an appreciable rise in the platelet count during the postoperative (nephrectomy, nephropexy and ureterotomy, exploratory laparotomy and herniorrhaphy) period of hospitalization or during the two months following discharge.

**Rapid Typing of Pneumococci.**—Vinograd and her collaborators compared the results of typing pneumococci from laryngeal swabs obtained from children and infants by the Neufeld technic with those obtained by inoculation of a mouse, using microscopic and macroscopic agglutination technics and examination of blood agar plates streaked with the original material. For the Neufeld procedure, the tube of broth containing the original material was centrifuged at high speed for from five to ten minutes to sediment the particles of sputum, pus cells and organisms. All but 1 or 2 drops of the supernatant fluid was decanted and retained for further use. A loopful of the sediment was mixed on a cover slip with two or three loopfuls of type-specific rabbit serum and a loopful of Löffler's alkaline methylene blue. The preparation was then examined as a hanging drop under oil for the swelling phenomenon. To facilitate typing, preliminary tests were made with grouped serums by both the Neufeld reaction and the microscopic slide agglutination method. Last, a dilution streaking was made of the original specimen on a blood agar plate to indicate the kind and also the approximate number of organisms present. The Neufeld reaction gave positive results for 100 of 106 patients. The results were called positive in the sense that either a type of pneumococcus was identified directly by the Neufeld reaction or pneumococci were not obtained by any method. The majority of results showed a high degree of correlation between the Neufeld test and the other methods of typing. By most of the methods a specific type of pneumococcus was determined. There were seven patients from whom type-specific pneumococci were obtained only by direct typing by means of the swelling phenomenon, the methods of inoculation of a mouse and the plate method revealing no pneumococci. In only six cases in which other methods disclosed a specific type did the Neufeld reaction fail to indicate a type. Direct typing by the Neufeld method has the advantage of speed over other methods by shortening the interval of typing from approximately six to twelve hours in a large proportion of cases in children to less than one hour.

#### American Journal of Medical Technology, Detroit

2: 81-120 (May) 1936

\*Laboratory Findings in Leukemic States. R. R. Kracke and Hortense Garver, Emory University, Ga.—p. 81.

Spirochaeta from Blood and Tissue Cultures of Diseased Chickens. E. Redowitz, Philadelphia.—p. 92.

Pathogenic Fungi: Studies from Two Fatal Cases. Fanny Bell Warnock, Champaign, Ill.—p. 98.

Cytology of Spinal Fluid. Phyllis Stanley, Newark, N. J.—p. 106.

**Laboratory Observations in Leukemic States.**—Kracke and Garver point out that recent research indicates that in leukemias of all forms heterophile antibodies are either absent or are found in low titers (generally but not necessarily below the normal level). This facilitates the differential diagnosis between certain forms of leukemia and infectious mononucleosis, which in the early stages are often clinically and hematologically identical. Leukemia may be excluded, but a low titer does not establish its existence. A titer of 1:128 in the absence of recent horse serum therapy and in the presence of suggestive symptoms almost invariably establishes the diagnosis of infectious mononucleosis. A titer above 1:128 is considered positive for this disease even if there is a history of serum injections, unless the patient has serum sickness (urticaria) at the time of examination or has only recently recovered from this condition. In severe cases the titer may reach

1:4,000. In a leukemia with a low cell count it is most important to be able to recognize the immature, blast forms and not confuse them with lymphocytes. The laboratory aids to this end should include careful morphologic study, peroxidase reactions, indophenol blue synthesis and studies on concentrated specimens of blood. The diagnosis of leukemia should never be made in a laboratory. This can be done only by the physician.

 Tuberculous Tracheobronchitis: Report of Case. P. D. Crimm and J. W. Strayer, Evansville, Ind.—p. 441.  
 New Thoracoplasty Screen. W. D. Thompson Jr., St. Louis.—p. 444.

**Management of Bilateral Cavernous Tuberculosis.**—Coryllos and Ornstein believe that no bilateral case should be considered hopeless and unsuitable for collapse treatment because of the fact alone that it is bilateral; even if only one lobe is still healthy, treatment should be instituted. In 238 cases of bilateral pulmonary ulcerative tuberculosis they could not induce pneumothorax or the cavities could not be collapsed because of the presence of adhesions. The additional application of intrapleural pneumonolysis and thoracoplasty was considered. The results obtained show that from 40 to 60 per cent of these patients, thus far considered hopeless, can be rescued and their sputums rendered persistently bacillus free. The severe restrictions for surgical treatment commonly applied today to these patients are not justified. Evidence is presented in favor of the conception that no case should be considered hopeless only because it is bilateral, even when bilateral pneumothorax did not succeed in collapsing the cavities. The importance of a modified technic of closed pneumonolysis is stressed and the efficiency of bilateral thoracoplasty in selected cases is insisted on. The surprisingly small amount of healthy pulmonary parenchyma necessary for continuation of moderately active life was a great aid in allowing the authors to collapse large areas of diseased lung successfully.

**The Vagus and Its Relation to Surgery of Lung.**—In the course of his experiments on laboratory animals on the relation of the vagus to lung surgery, O'Shaughnessy also made

observations on the sensitivity of the lung root in man. During an intervention on the thoracic esophagus, a patient whose general condition had remained good despite a wide exposure of the mediastinum manifested great distress as a separation of the esophagus from the left main bronchus was attempted. As soon as the attempt was abandoned the general condition returned to its former state, and recovery from the exploration was uneventful. In three cases the lung root was explored and a ligation of the pulmonary vein after the manner of Kerschner carried out. No cardiac or respiratory distress was observed except in one case, in which retraction of the heart by the hand of the assistant produced a marked but temporary bradycardia. In these cases a swab soaked in 15 per cent cocaine was applied to the area without harmful effects, but, in view of the author's experimental observations, some other method of local anesthesia will be adopted. During an operation for the open division of adhesions between the lung and the thoracic wall, the patient being anesthetized by N-methylcyclohexylmethylmalonylurea, he had occasion to observe that the region of the lung root was highly sensitive. The vagus is an important sensory nerve, and it is an advantage to prevent nociceptive impulses from passing along it. At the same time, blocking of the vagus stem is not a safeguard against reflex disturbances while operating in especially sensitive regions, such as the lung root; respiratory reflexes are certainly abolished, but cardiovascular reflexes remain. Safety can be attained only by a local infiltration of the operative field. Total spinal anesthesia in man proved a satisfactory anesthetic for some operations on the chest wall, such as thoracoplasty, but it was not used in any operation on the lung. Experimental results suggest the trial of total spinal anesthesia for intrathoracic operations.

**Auricular Fibrillation Associated with Apoplexy.**—In a study of more than 1,000 cases of apoplexy Perkins observed that one out of every eleven admitted to the hospital had auricular fibrillation. Although many of these patients had been treated previously for heart disease or hypertension, it was quite impossible to determine the status of the cardiac condition just prior to the cerebrovascular accident. Early in the intensive study of patients with apoplexy it was noted that in many instances the auricular fibrillation disappeared before digitalization was attempted. In five cases of hemiplegia, a careful history showed that the acute onset was typical of coronary thrombosis. There was a complete necropsy performed in three of the cases in which death occurred from coronary thrombosis. The cerebral condition was typical of embolism, involving branches of the middle cerebral artery. In the cases of cerebral infarction from embolism due to intracardiac thrombosis, it is difficult to determine the origin of the embolus, when auricular fibrillation is present. No one condition or single set of circumstances can explain the development of auricular fibrillation in all cases. Three possibilities are suggested: (1) disruption of the normal processes of conduction within the auricles as a result of some pathologic change in the muscle fibers, (2) alterations in the metabolic activities of the heart and (3) alterations in the nervous influences, especially conditions of increased vagal tone. Any one or all three elements may be responsible in a given case. These patients generally belong to one of the following groups: the chronic cardiovascular-renal type, generalized arteriosclerosis or senile heart of the paroxysmal type associated with hypertension. If a careful history of the onset of the vascular accident is obtained, it is noted that it occurred during physical activity or exertion, a condition which favors an increase in the cardiac arrhythmia and predisposes to embolism instead of thrombosis. The clini-

cal picture presented by the patient is that of an infarction rather than hemorrhage. The immediate care of these patients should be placed in the hands of the internist, as the problem of greatest importance is the treatment of the crippled heart. The repair of the cerebral infarction as well as the favorable prognosis depends on the improvement in the general circulation, which is governed by the cardiac status. When the patient has improved sufficiently to be discharged from the hospital, he should be instructed as to the importance of the observation and care of his cardiac condition in order to prevent, as far as possible, its recurrence.

**Congo Red for Control of Bleeding.**—Graves and Kieham call attention to the use of congo red as a hemostatic agent. They have employed it for the relief of bleeding in renal injury, bilateral renal and ureteral calculi, chronic pyelonephritis, vesical calculus, benign hypertrophy of the prostate, tumor of the bladder, urethral trauma and the like. There have been no untoward effects in any instance, following the injection of 5 cc. of congo red (1 ampule of a sterile isotonic solution) or 10 cc. given intravenously. This may be repeated if necessary. Rossak states that occasionally patients complain of palpitation and lower abdominal pain, but the authors have not observed such disturbances. Even the accidental paravenous injection of the dye has resulted in no ill effect other than a persistent red discoloration of the skin. Congo red has been found to be most useful in cases of acute bleeding in individuals who still possess at least a relatively normal coagulation mechanism, and less effective in such chronic persistent bleeding as often occurs from pyelonephritis or malignant tumors of the urinary bladder. Whether its lack of success under such circumstances is due to local or general causes is not known. Obviously it will be of little or no value in actual blood disease. The authors have used it as a prophylactic agent following prostatectomy and transurethral resection, when unusual bleeding has been encountered. Some of their colleagues have administered it with marked success in severe epistaxis and hemorrhage after tooth extraction.

**Cardiac Dyspnea.**—Levin points out that, since failure of the left side of the heart with its dyspnea, râles and dulness is nothing more than an obvious dropsy of the lungs (water

retention), its proper treatment should include the use of diuretics. Because results have not been consistent with the use of oral diuretics, he has recently been using salyrgan and, to a lesser extent, mercupurin (the sodium salt of trimethylcyclopentane-dicarboxylic acid-methoxy-mercury-allylamide-theophylline) intramuscularly. The use of mercurial diuretics is indicated in early left ventricular failure when the signs and symptoms continue after a reasonably short period of rest and digitalis therapy, and, if urine output continues to fall much below liquid intake in spite of thorough digitalization, the patient is headed for generalized failure. The contraindications may be said to be renal and gastro-intestinal. Severe nephritis is a definite contraindication. The intravenous use of salyrgan or mercupurin is almost impossible when mercurial diuretics are required over a period of months or longer; therefore the intramuscular route has been chosen as best fitted to meet the therapeutic requirements of most patients. The anterolateral aspect of the thigh rather than the gluteal region is the site of choice, particularly in a bedridden patient. An injection of 1 cc. is followed on the third day by 2 cc., provided no gastro-intestinal or renal dysfunction develops. This dosage is maintained only as long as it remains effective. When it is noted over a period of from two to four days that the net water balance is unfavorable, the dosage is raised to 4 cc. The frequency with which injections are repeated depends on the status of the water metabolism. The patient is asked to chart his liquid intake and output. The former is usually limited to not more than 1,500 cc. When the level of the urinary output falls below the intake, another mercurial injection is needed. The measurements are continuous and give the clue to each succeeding treatment. Gradually, in favorable cases, the interval between injections increases as the efficiency of the kidney improves. A maintenance dose of 4 cc. once a month is generally sufficient to keep the heart well compensated. In most cases it has been deemed unwise to risk a relapse by ceasing entirely the use of the diuretic. The prolonged use of acid salts as an adjunct in the diuretic treatment of left ventricular failure has not proved satisfactory. The use of from 6 to 10 Gm. of an ammonium salt soon renders all food unpalatable and may produce nausea and vomiting. The additional quantity of urine excreted by the use of these salts has not been significant enough to warrant their routine use.

**The Genesis of Gallstones.**—Bockus and his associates analyzed the clinical and laboratory data that could be considered pertinent to the genesis of the common types of calculi in 156 cases of proved gallstone disease. The cases have been segregated into three groups, depending on stone types: pure

radiate cholesterol stones, calcium bilirubinate cholesterol (mixed) stones and pigment stones. A comparison has been made between the observations in the first two groups, particular attention being paid to an analysis of factors bearing on infection and disturbed cholesterol metabolism in gallstone genesis. It is concluded that gallbladder infection and cholecystitis probably do not play an important part in the genesis of the common mixed stone. Associated infection is more commonly observed in the calcium bilirubinate cholesterol stone group than in cases of the pure radiate cholesterol stone. Evidence is given which suggests that the concomitant inflammation of the gallbladder so frequently encountered results from rather than causes the deposition of stones. A mobilization of all available information fails to establish the mechanism by which a disturbance of cholesterol metabolism is responsible for the deposition of choleliths. However, the data submitted suggest that an alteration in cholesterol metabolism plays an important part in the genesis of both the pure cholesterol and the ordinary mixed gallstone.

#### Surgical Measures for Prevention of Gas Gangrene—

During the last two years at the Shreveport Charity Hospital and in his private work, Caldwell has encountered nineteen cases of gas gangrene of the extremities with ten deaths. The nine patients who lived escaped death only by the sacrifice of limbs. A careful review of the case records reveals the probability that, with proper management eight of the ten deaths might have been prevented and six of the nine amputations might have been avoided. This mortality rate, compared with 48.5 per cent during the World War and from 7 to 32 per cent as shown by several reports during recent years in civil practice, indicates that some fundamental surgical principle is being violated. Correct surgical principles for the prevention and control of gas gangrene were carefully worked out during the World War, and these have not changed. The whole difficulty is that these principles have been forgotten or that a new generation of surgeons has grown up who are not sufficiently impressed with their importance. In discussing the surgical measures for the prevention and treatment of gas gangrene, the author reviews briefly the bacteriology and pathology of the disease. Thorough exposure and removal of all damaged muscular tissue rob the bacillus of its culture mediums and if the wounds are left wide open, such anaerobes as may remain cannot gain a foothold because of the presence of oxygen. The author states that, had these measures been faithfully applied in the nineteen cases presented, the deaths might have been reduced to two or less, and the amputations to at least three on the patients who recovered. Instead, however, the debridements almost invariably were followed by culture of the wounds with subsequent development of gas gangrene and the amputated stumps were closed with fatal results. Perfringens antitoxin is a valuable prophylactic and therapeutic adjunct but in no way displaces proper surgical measures.

#### Hemorrhage from Ruptured Corpus Luteum Cyst—

Jones reports three cases of massive abdominal hemorrhage from ruptured corpus luteum cyst. In each instance there was excruciating pain in the lower part of the abdomen near the midline. This pain lasted from two to twenty minutes and then was followed by from thirty minutes to one hour of complete absence of any symptoms at all. Then followed, in regular sequence, first a generalized tenderness in the lower part of the abdomen, next a rigidity of the muscles more marked on the affected side, next abdominal distention, and then the usual symptoms of shock, which follow hemorrhages. There was no nausea or vomiting until hypodermics were used, but two authors report the presence of nausea. The cervix appeared to be normal, the uterus was normal in size and freely movable, in the tubo-ovarian areas there seemed to be some tenseness but very little resistance and no distinct tender areas. The accompanying pressure on the abdominal wall seemed to elicit far more tenderness than the vaginal observations justified. The abdomen presented rigidity of the muscles, distention, first confined to the area below the umbilicus and later to the upper part of the abdomen. There was a dull flat note on percussion. The blue umbilicus was not noticed. The general symptoms, such as fainting, pallor, sweating and rapid pulse, are the usual chain seen in hemorrhagic shock. The differential diagnosis brings to mind (1) ectopic pregnancy, (2) appendicitis, (3) traumatic rupture of a viscus and (4), in one case, ruptured gallbladder. It would seem that appendicitis could be ruled out and possibly traumatic rupture, and it truly seems that the confusion with gallbladder disease would be far fetched in most cases, but the author does not see how the possibility of ectopic pregnancy could be excluded before operation. There is little need for a differential diagnosis between these two entities, as the operative indication is the same. The patients' ages were 22, 24 and 28. Not more than six hours elapsed from the onset of the first symptom to the time of operation in two of the cases yet there was more than three pints of liquid blood and half that much of clotted blood in the abdomen in each case. None of the patients gave a history of any serious menstrual disorders. The hemorrhages occurred at various times during the menstrual month, one, five days after a normal period, one, sixteen days, and the third, twenty one days. The main point in diagnosis is that, if a case presents many of the symptoms of an ectopic pregnancy but the classic bulging mass is absent on vaginal examination, it should be remembered that massive hemorrhage can occur from a graafian follicle or a corpus luteum cyst, and immediate steps should be taken to handle the case as one of abdominal hemorrhage from any cause.

**Virus Etiology of Lymphocytic Meningitis.**—Findlay and his associates isolated a virus from the cerebrospinal fluid of two patients suffering from obscure nervous symptoms associated with an increase of lymphocytes in the cerebrospinal fluid. The virus inoculated intracerebrally into monkeys, mice, rats and guinea-pigs causes a fatal infection: post mortem there is intense infiltration of the meninges, choroid plexus and ventricles with round cells. When inoculated intraperitoneally into mice, the virus causes no symptoms but remains for some weeks in the spleen and kidneys. It is excreted in the urine of mice and can pass through the lightly scarified skin. A similar virus has been isolated from apparently healthy mice. The human and mouse strains isolated in this country behave in animals in the same way as the American virus described by Armstrong. Serums from human cases in this country contain immune bodies to the American virus and to the English mouse strain virus. There is thus evidence that this virus infection is widely spread on both sides of the Atlantic. The evidence here brought forward shows that a virus infection is present in mice and possibly also in rats and that this virus can be communicated to man. The exact port of entry in human cases has not yet been determined, but judging from analogies with infection by *Leptospira icterohaemorrhagiae* it is likely to be the skin or mucous membranes.

\*Control of Bleeding in Nose and Throat Operations. R. G. Brown.—p. 359.  
Laboratory Investigation of Suspected Psittacosis. F. M. Burnet.—p. 363.

**Control of Bleeding in Nose and Throat Operations.**—Brown discusses the physiology of blood coagulation and the theoretical methods of its control. Accepting a prothrombin deficiency as the causal factor in hemophilia, the various lines of treatment of deficiency in blood coagulation fall into three groups: (1) the introduction of normal prothrombin from some

foreign source, (2) the introduction of any of the other coagulative elements, thus increasing the coagulability by the law of mass action, and (3) the introduction of some foreign substance in the hope of stimulating more rapid coagulation. Some of the most commonly used coagulating substances are discussed. The blood clotting time may be estimated in one of several ways, and the method selected is not so important as one's familiarity with a particular method and the use of that method only. An average of five minutes is taken as a safety mark and may be considered normal. Perhaps the simplest method of estimation is by the capillary tube. The estimation of the bleeding time is of more value than the clotting time. Normally the bleeding time should be from two to three minutes. The author stresses three points which he feels are not as commonly recognized as their importance deserves: 1. Faulty technic is the commonest cause of postoperative bleeding. 2. Bleeding not infrequently appears coming from beneath a clot. It is essential to remove this clot before one can successfully deal with it. Removal of the clot by wiping off in bleeding from a tonsil bed or, in bleeding from a nose, by washing out the clot or sometimes by simply blowing out the clot, may cause cessation of bleeding by allowing clots to form in the ends of the bleeding vessels. 3. Placing the patient in an upright position after a nose or throat operation is a big factor in the prevention of bleeding from small veins, which are the vessels mainly responsible. In such a posture the patient's blood pressure may be decreased; the "tone" of the cut ends of the vessels is increased, thereby more readily aiding constriction. Moreover, there is less pressure of venous blood above the bleeding points.

**Sprains and Strains.**—Heald gives rules for the treatment of delayed recovery cases of strains and sprains. 1. Injured parts that are persistently painful on waking after they should normally be well, which ease up during the day, require general treatment or elimination of a focus of infection. 2. Injured parts worse on getting warm in bed and waking patients about 5 a. m. should be treated for gout, whatever the family history. 3. Injured parts that are free and painless at all times and with all movements except one have a critical adhesion and will repay mobilization. 4. Injured muscle groups that develop residual spots of pain, which on being touched radiate this pain, have an adhesion of a nerve, and only special technics, such as galvano-acupuncture, are of any use. 5. Parts remaining persistently thickened and boggy long after they should have recovered are suggestive of a gonococcal basis. The practitioner is urged therefore to give his sprains and strains, on the day of injury if possible, the simple direct current or to send the patient to the technician with a fully detailed prescription.

- Modern Operation for Cataract: Total Extraction of Crystalline Lens. P. Bonnet and L. Paufigue.—p. 237.

**Hyperthermic Syndrome in Nurslings.**—Genet states that the so-called syndrome of hyperthermia and pallor is a rare but serious complication resulting from operations performed on infants. It is characterized by a progressive elevation of temperature, which develops five or six hours after the operation. The rise in temperature continues until it reaches 41 or 42 C. (105.8 or 107.6 F.) or even more and is accompanied by a marked pallor of the skin. Death may occur in less than thirty hours, but recovery is possible. The pathologic anatomy based on a few necropsies has revealed a constant sterility of blood and intact kidneys. There is, in fact, little that is abnormal in the pathology—nothing, in fact, to explain death. A probable pathogenesis is the irritation of the thermic centers, which are incompletely developed in the nursling. Such irritation is followed by a disturbance in the secretion or in the cycle of secretion of the cerebrospinal fluid at the level of the third ventricle. The medical treatment is to counteract the hyperthermia and to sustain the heart. Lumbar puncture has given good results in some instances.

- \*Iliosacral Reticuloplasmocytomas. L. Sabadini, J. Montpellier and Chéchan.—p. 526.

**Iliosacral Reticuloplasmocytomas.**—Sabadini and his collaborators state that clinically the plasmocytoma at first invades the osseous medulla under the form of small tumors, which finally fuse. The invaded osseous tissue is quickly destroyed. Most frequently the tumors are multiple and distant from one another. The cranium may become perforated. In the vertebrae the plasmocytomas completely destroy one or more vertebrae and can invade the spinal canal. The onset is exceedingly insidious. Sometimes the tumor appears as a nodule about the size of a nut, an egg or a small mandarin. Occasionally the initial signs are facial paralysis or medullary compression. General examination of the patient is often negative. Examination of the urine is especially important in the diagnosis. In 80 per cent of their cases, Bence Jones protein is present. They conclude from their studies that the tumors are rare and that the origin of both the normal plasmocyte and plasma tumors is uncertain. In the case which they reported all the transition stages between the reticulocyte cell and the tumor-like plasmocyte were found. This naturally suggests the reticulocyte origin of these tumors. The matter, however, is not yet certain.

**Mountain Climate as Therapeutic Factor.**—Campbell discusses the physiologic action which high altitude exerts on the organism of a person who is accustomed to low altitudes. He says that the change to high altitude results in a change of reaction. He thinks that a sojourn at a high altitude is desirable for all disorders in which a change of reaction is desirable. However, whether induced by medicaments, by balneologic or climatologic methods or by other modes of stimulation, this change in reaction requires certain reserve powers

in the organism in order to be beneficial. Where such reserves are lacking, a favorable effect cannot be expected or the influence may even be harmful. Even the quiet sojourn in the high mountains makes greater demands on the organism of one accustomed to low altitudes. All life processes are intensified, a factor which, in case of reduced reactivity, may already have a curative effect. However, the high mountain climate should also increase the resistance by the systematic increase in exertion. Since the therapeutic effect of the high altitude climate is dependent on an adequate amount of reserves, it is contraindicated in decompensated circulatory disturbances and in states of extreme exhaustion of organic origin. However, the author denies that the high altitude climate is harmful for all patients with heart disease. Patients with compensated cardiac defects or with disorders of the cardiac muscle not only tolerate the high altitude climate but are favorably influenced by it. The intensification of the life processes at high altitudes occasionally intensifies formerly mild symptoms, so that obscure cases become suddenly clarified. Insufficient attention is given to the rôle of nicotine in acclimatization. He says that symptoms of nicotine poisoning develop more readily at high altitudes. He mentions that tuberculosis, bronchial asthma, neuroses, compensated circulatory disorders, hypertension, hypotension, mental exhaustion, and so on, are cured more rapidly than when the patient remains in low altitudes.

**Blood Changes After Exertion at High Altitudes.**—Jezler and Vischer studied the changes in the blood picture that appear after prolonged ski runs (from five to nine hours' duration) in the high mountains. They found that in general the changes in the white blood picture are not great. The increases never reach the values that are observed after prolonged ski runs at low altitudes. Erythropoiesis seems to be greatly influenced by exertion at high altitudes; however, the increase in mature erythrocytes is not proportional. The authors suggest that the increased functional requirements might reduce the life span of the erythrocytes. The specificity of the stimulus of high altitude is indicated by the number relations of the leukocytes, for here the reaction capacity seems to decrease with the higher altitude. In this connection, the authors cite other observers who observed entirely normal leukocyte values after exertions at altitudes of 6,000 and 7,400 meters.

## Rivista di Patologia e Clin. d. Tubercolosi, Bologna

10: 221-292 (April 30) 1936

- \*Monocyte-Lymphocyte Ratio in Pulmonary Tuberculosis. L. Bresci.—p. 221.
- Pulmonary Moniliasis: Case. F. Balestrieri.—p. 229.
- Pathogenesis of Tuberculous Hemoptysis from Clinical Point of View. I. Cornia.—p. 233.
- Hematogenous Pulmonary Tuberculosis in Children and Adolescents. E. Filla.—p. 242.
- Weltmann Reaction in Artificial Pneumothorax. Lydia Barsottelli and Dina Poggioni.—p. 257.
- Artificial Pneumothorax in Dispensaries. G. Rambelli.—p. 264.

**Monocyte-Lymphocyte Ratio in Pulmonary Tuberculosis.**—Bresci aimed at verifying the conclusions previously reported as to the value of the monocyte-lymphocyte ratio in diagnosis and prognosis of pulmonary tuberculosis. He determined the monocyte-lymphocyte ratio in two groups of patients suffering from pulmonary tuberculosis of the benign and severe forms. The monocyte-lymphocyte ratio was low in the blood of patients of the first group at the first determination, and still lower at the following two determinations. The initial figures of the ratio never exceeded 0.4 in patients of this group. The ratio was high in the blood of patients of the second group at the first determination, and still higher at the following determination. The initial figures were never under 0.5. Figures as high as 2 and 2.75 were obtained in grave cases. The author says that his results confirm the statements previously made in the literature as to the existence of a direct relation between the tuberculous process and the evolution of the monocyte-lymphocyte ratio. The blood mirrors the histocytologic evolution of the tuberculous process with an increased monocytosis and a decreased lymphocytosis in grave cases and the opposite monocyte-lymphocyte proportion in benign cases. The author emphasizes the diagnostic and prognostic value of the monocyte-lymphocyte ratio and the advantage of this procedure over the separate counting of these cells.

Foot Blisters and Their Treatment. W. Barthel.—p. 603.  
Contracture in Paralysis and Its Orthopedic Treatment. J. Schüller.—p. 606.

**Cause of Death in Air Embolism.**—Pfanner shows that, if air enters the heart and there comes in contact with blood, the rhythmic contractions of the heart beat the blood into foam. As the volume of the foam increases, the proper systolic contraction and evacuation of the heart become impossible. The heart can neither expel the foam nor compress it. Thus the heart has to handle a considerable excess load. The right side of the heart, with its relatively weak muscular apparatus, gradually weakens and death results from interruption of the circulation by paralysis of the right side of the heart.

**Traumatic Ossifying Myositis After Dislocation of Elbow.**—Böhler describes the history of a case of dislocation of the elbow that came under his observation four months after the injury. The elbow showed thickening and felt hard, and movement was greatly restricted. Roentgenoscopy disclosed extensive ossification in the region of the brachial and triceps muscles. The author asserts that he has seen many similar cases of dislocation of the elbow in which extensive ossification processes developed in muscles and ligaments. The after-treatment had been energetic in all these cases. He cites several authors who believe that ossifying myositis results from almost all dislocations of the elbow. In the author's own material of twenty-nine cases there were only three in which a mild form of ossifying myositis developed. He reduces the dislocation under local or general anesthesia by means of traction on the flexed elbow and then puts the arm into a plaster-of-paris cast reaching from the shoulder to the fingers. This cast is usually left on for three weeks. Immediately after the cast has been put on, active movements are made in the shoulder and finger joints. After the removal of the cast the elbow is always soft, whereas in case of massage treatment it is usually hard and thickened. The author advises that the after-treatment should consist only of active movements and that all other modes of treatment should be avoided. Two of his three patients in whom a slight ossifying myositis developed had been given massage treatment and the third patient had performed hard physical labor immediately after removal of the cast. The author observed ossifying myositis also in some cases in which the reduction had been done either in hyper-extension or several days after the injury. The author concludes that the ossifying myositis after pure dislocations of the elbow which are at once carefully reduced is not a result of the injury but rather of a mode of treatment in which massages and passive movements are begun early.

Insulin Therapy of Schizophrenia. H. Strecker.—p. 649.

**Diagnosis of Multiple Myeloma by Sternal Puncture.**—Schulten reports the clinical histories of two patients with multiple myeloma in which the diagnosis was made possible by sternal puncture. After emphasizing the importance of sternal puncture in cases of this nature, he stresses that observation of the fresh smear discloses that the typical myeloma cells do not resemble the myelocytes or the myeloblasts. Moreover, he is convinced that they are not one of the links in the developmental chain of the myeloleukocytes, erythrocytes or megakaryocytes and that they are not reticular cells. At first sight the cells resemble most closely the plasma cells, except that they are larger, the plasma is not quite so strongly basophil and the perinuclear transparency, the wheel-spoke nucleus and the capacity to be stained by specific dyes are lacking.

One who frequently inspects bone marrow pictures knows that such cells occur occasionally in healthy persons and in patients with other disorders. As a rule they are classified with the plasma cells. The author concedes that a similarity with the plasma cells cannot be denied, but he says that it has not been proved as yet whether a genetic relationship to the plasma cells exists. Until their origin has been explained, he advises the acceptance of Wallgren's suggestion to refer to them as "myeloma cells."

\*Lift Reaction as Aura in Tumor of Temporal Lobe. H. Hoff and O. Pözl.—p. 461.

**Lift Reaction as Aura in Tumor of Temporal Lobe.**—Hoff and Pözl report the history of a woman, aged 39, who seven years previously had had her first epileptic attack. After that she had epileptic attacks three or four times each year, but during the last year they had become more frequent. The woman stated that before these attacks she frequently has the feeling of increasing in size, as if her head would reach the ceiling; at other times she has the feeling of going up in an elevator, followed by a feeling of going down again. These two types of aura recurred alternately. During the last year the patient has had frequent attacks of headache in the occiput, also nausea and vomiting. The authors found a reddish tumor on the first temporal convolution, but, since its limits could not be defined, only a portion of it was extirpated. The patient died twelve hours later. The necropsy revealed an infiltrating glioma in the anterior end of the right temporal lobe. Analysis of the manifestations of the aura reveals that they are in accord with the stretching phases of the lift reaction in quadrupeds (described by Magnus); that is, they are a reaction of the semicircular canals to progressive movements. Thus the aura had the character of a supravestibular disturbance.

**Pulsation of Veins of Extremities.**—Teufl found that a retrograde pulsation, and one which is somewhat retarded in comparison with the arterial pulse, of the normal veins of the upper and of the varicose veins of the lower extremities is a regular occurrence in organic as well as in relative tricuspid insufficiency, which in turn is unusually frequent in cardiac decompensation. The analysis of the venous pulse of the extremities, which, if done in profile illumination, is more readily accomplished than the evaluation of the pulsation of the jugular vein, and which in many cases is easier and more reliable than the palpation of the pulse of the hepatic veins, by the demonstration of its constancy and of its undiminished intensity permits the diagnosis of organic tricuspid insufficiency, independent of the compensatory condition of the heart, whereas its disappearance during the subsidence of the decompensatory manifestations indicates a relative muscular tricuspid insufficiency. The constant venous pulse which varies in intensity is an unfavorable prognostic sign of relative insufficiency of the tricuspid valve, whenever the decompensation cannot be influenced. In cases in which organic tricuspid insufficiency has been demonstrated, the weakening of the venous pulse of the extremities is a sign that the cardiac action is becoming weaker and indicates an unfavorable prognosis. Isolated pul-

sation of the varicose veins, which is largely dependent on the intra-abdominal pressure, and the respiratory phenomena which show a paradoxical behavior for the veins of the upper half of the body and predominate over the pulsatory manifestations, even if the pulsation is retrograde and retarded, militate against a tricuspid insufficiency and are to be traced to a direct or indirect central involvement. The surprising contradiction between a clearly retrograde venous pulse in the region of the upper extremity and a nearly absent pulse of the varicose veins, in the presence of abdominal stasis, is an important argument in favor of the difficult diagnosis of concretion or accretion of the heart. The absence of the venous pulse in the extremities, in patients with severe cardiac insufficiency and peripheral stasis, disproves dilatation of the right side of the heart and suggests a mechanical throttling of the venae cavae, which in turn might be caused by a pericardial exudate or by a space limiting mediastinal process. The penetrating venous pulse is the result of an especially high pulse pressure and, as a rare occurrence in aortic insufficiency, it is without clinical significance; but the retrograde venous pulse of the extremities is of considerable significance.

### Novyy Khirurgicheskiy Arkhiv, Dnepropetrovsk

35: 163-312 (No. 138) 1936. Partial Index

Organization of Campaign Against Cancer. A. A. Epshteyn.—p. 163.

\*Pathogenesis of Gynecomasty. D. G. Goldman.—p. 181.

\*Results with Parathyroidectomy for Ankylosing Polyarthrit. P. S. Fedorov.—p. 208.

Rabl Method of Treatment of Rachitic Deformities of the Lower Extremities. A. I. Kogon.—p. 222.

Prolonged Intravenous Drop Infusion. K. G. Tagibekov.—p. 235.

**Pathogenesis of Gynecomasty.**—Goldman has collected seventy-two cases of gynecomasty among patients treated from 1925 to 1935 at the marine hospital of Kronstadt. Operation was performed in sixty-eight of these cases. Enlargement of both breasts was present in twelve (16.7 per cent). Pressure on the glands yielded a secretion in eleven. Pathologic alterations in the sexual sphere were present in sixteen (22.2 per cent). A female type of distribution of the suprapubic hair and a wide pelvis was present in eleven. The development of the sexual organs was normal in all but ten cases. Sexual function was normal in all save three cases, in which libido was diminished in two and absent in one. Trauma of the breast was an etiologic factor in six. The reaction of Manoiloff was made in twenty-eight cases and was found to be of the female type in twenty-six. The author found in his animal experiments that castration of males (rabbits) followed by transplantation of ovaries (from rabbits) caused a hypertrophy of the mammary glands. Parenteral introduction of solution of posterior pituitary produced a hypertrophy of the mammary glands in rats and white mice. Injections of ovarian or mammary extracts had no such effect. The author is of the opinion that the existence of an internal secretion of the mammary gland has not been demonstrated. Histologic studies point to the breast as a gland of external secretion. The author concludes that gynecomasty is frequently unaccompanied by any abnormality in the sexual sphere. There may exist hyposexuality and hypothyroidism in a number of cases. Histologic studies reveal a well developed glandular apparatus but no secreting cells.

**Parathyroidectomy in Ankylosing Polyarthrit.**—Fedorov reports 121 parathyroidectomies performed at the Mechnikov Hospital (Leningrad) from 1926 to 1932. Oppel suggested in 1926 that ankylosing polyarthrit is a disease of infectious origin characterized by inflammatory changes of the synovial membrane and the surfaces of the bones of a joint. He found that the blood calcium of patients suffering from this form of polyarthrit is increased above the normal and that the calcium deposited on the inflamed joints led to ankylosis. The condition is one of hypercalcemia, the opposite of the one found in tetany, which is characterized by hypocalcemia. Oppel formulated the theory that hyperfunction of the parathyroid tissue was the basis of the condition. He performed parathyroidectomies and found that the muscular stiffness, joint stiffness and pain were relieved. The disease affects preponderantly young men between the ages of 20 and 40. There were only two women in this series. The disease is characterized by a progressive involvement of the joints, the

vertebral column being the seat of predilection. The disease must be differentiated from deforming polyarthrit, in which ankylosis is due to exostoses of the vertebral bodies. The muscles become stiff and woodlike. Forty-eight patients of a group of ninety-three showed hypercalcemia. The immediate effects of the operation were the relief of pain and stiffness. This was observed in seventy-nine out of 121 cases. The operation advocated is a unilateral parathyroidectomy and hemistrulectomy. Eighty-four cases were followed up for periods ranging from three to seven years. Improvement was reported in thirty-nine, arrest of the process in nineteen and progression of the disease in seventeen. The best results were obtained in cases of pronounced hypercalcemia. There were no deaths due to tetany.

### Finska Läkarsällskapets Handlingar, Helsingfors

79: 195-294 (March) 1936

\*Studies on Granulocytopenia. B. von Bonsdorff.—p. 200.

**Granulocytopenia.**—Of von Bonsdorff's fifteen patients, four were men and eleven women, ranging in age between 18 and 67, the majority being between 40 and 50. Five of the cases were previously reported and ten are now presented. He says that nine cases were more or less probably the result of aminopyrine. In three of these, of which two were fatal, antisyphilitic treatment with neoarsphenamine and preparations of bismuth was probably the cause. In one the disorder is ascribed to roentgen treatment given for polyarthrit, and in two, one with chronic intermittent course, the other also with recurrence, the etiology is unknown. In several cases in which the disturbance lasted a long time there was in addition to the granulocytopenia a more or less marked anemia. Cytologic examination of the sternal marrow carried out in eight cases showed abundant myelocytes and myeloblasts in the three patients who recovered, while in three of the five fatal cases the picture was dominated by reticulo-endothelial cells, partly of plasma cell nature, and in two the punctate was deficient in cells and contained mainly lymphocytes, monocytes and erythroblasts. The outcome of the sternal puncture is of great value in judging the prognosis; the blood picture affords no certain guidance in this respect. One case was clinically regarded as "noma" and the author is of the opinion that the necrosis of skin and mucous membrane formerly connected with the conception of "noma" is mainly the result of a more or less marked reduction in granulocytopenia, and in certain cases with leukemic picture perhaps also to a qualitative deficiency in the granulocytes. The good results obtained in two of the earlier cases by energetic liver treatment were not duplicated in later advanced cases, but liver therapy still seems the most promising. He advises against roentgen therapy.

Polymorphic Prurigo Aestivalis Treated with Intravenous Injections of Gold Chloride. S. Lomholt.—p. 353.

Acute Myeloblastic Leukoses: Two Cases. H. C. and R. Rask-Nielsen.—p. 360.

**Primary Cancer of Lung.**—Husted and Biilmann's material comprises forty-one cases, from 1911 to 1934. From 1924 on they find an absolute and a relative increase in the number of patients with primary pulmonary cancer; from 1929 to 1933 pulmonary cancer appeared in between 1 and 2 per cent of all necropsies and in 7.3 per cent of all cancer cases. The etiology is uncertain. Two cancers developed in patients with chronic inflammations of the lungs. No relation was demonstrable between the frequency of pulmonary cancer and the more extensive tarring of roads. The disorder may be latent a long time, and in about one fourth of the cases pulmonary symptoms were absent. Only about one third were diagnosed during life. The authors emphasize the importance of roentgen examination, particularly supplemented by bronchography. The primary tumor is almost always found centrally in the lung in close relation to the bronchi, and the large majority of these tumors apparently develop from the bronchi. The form, size and extent are extremely variable and complications common. Histologically, all forms of cell types and tumor structure are seen. Metastases are frequent and usually extensive; metastases to the central nervous system often occur.

PATHOLOGY AND PHYSIOLOGY—Chairman, W. E. Garrey, Nashville, Tenn.; Vice Chairman, R. R. Kracke, Atlanta, Ga., Secretary, J. J. Moore, 55 E. Washington Street, Chicago

NERVOUS AND MENTAL DISEASES—Chairman, Henry R. Viet, Boston, Vice Chairman, B. Landis Elliott, Kansas City, Mo., Secretary, Paul C. Bucy, 950 E. 59th Street, Chicago

DERMATOLOGY AND SYPHILOLOGY—Chairman, Paul A. O'Leary, Rochester, Minn., Vice Chairman, Charles C. Dennie, Kansas City, Mo., Secretary, Bedford Shelmire, 1719 Pacific Avenue, Dallas, Texas

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH—Chairman L. D. Bristol, New York, Vice Chairman, J. F. Bredeck, St. Louis, Secretary, I. C. Riggan, State Office Building, Richmond, Va.

UROLOGY—Chairman, Henry W. E. Walther, New Orleans; Vice Chairman, Nelse F. Ockerblad, Kansas City, Mo., Secretary, William P. Herbst, 1726 I Street, N. W., Washington, D. C.

ORTHOPEDIC SURGERY—Chairman, Fremont A. Chandler, Chicago, Vice Chairman, John Dunlop, Pasadena, Calif.; Secretary, Robert V. Funsten, University of Virginia Hospitals, Charlottesville, Va.

GASTROENTEROLOGY AND PROCTOLOGY—Chairman, Louis A. Bue, Rochester, Minn., Vice Chairman, Henry L. Bockus, Philadelphia, Secretary, A. H. Aaron, 40 North Street, Buffalo

RADIOLOGY—Chairman, Ross Golden, New York; Vice Chairman, B. R. Kirilin, Rochester, Minn., Secretary, John T. Murphy, 421 Michigan Street, Toledo, Ohio

# JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE, 1936

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1926. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

## SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ME," Medical Economics; "ab," abstract; the star (\*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2320.

sugar, increase during renal diseases, [Oefelein] 1862—ab  
sugar, preoperative and postoperative, 230  
sugar, relation to glycosuria, 307  
sulfatemia in kidney disease, [Øllgaard] 2116—ab  
supply (new) to heart, developed by operation, [Beck] 75—ab  
supply of rat tumors, effect of stoppage, [Chambers] 1428—ab  
Tests. See Blood group  
thiocyanates, estimation in hypertension, [Barker] \*762  
Tubercle Bacilli in. See Tubercle Bacillus  
urea clearance, formula for determining, 484, (correction) 635  
urea, hyperazotemia (postoperative) and stagnant gastric content, [Antonucci] 1770—ab  
urea nitrogen by direct nesslerization, [Breuer] 421—ab  
urea, nonurate azotemia and liver extract treatment, [Nonnenbruch] 580—ab  
urea, postoperative nonprotein nitrogen retention, 1931  
Velocity: See Blood circulation  
Vomiting of: See Hematemesis  
water concentration in pregnancy, [Oberst] 1037—ab  
water content factor in anemia of pregnancy, [Feldman] 1761—ab  
what sodium citrate solution is isotonic to? [Hirschfeld] 1434—ab
- BLOOD PRESSURE**, Arterial. See Blood Pressure, high  
capillary (cutaneous), new method for determining, [Baumberger] 335—ab  
changes in pregnancy, 2025  
changes, significance, 1840  
erythrocyte relation to, [Dolcs] 421—ab  
estrogenic substance effect on, [Steinhamm] 1526—ab  
fever therapy effect on, [Desjardins & others] \*697  
high arterial, and cholesterolemia, [Domenech] 580—ab  
high arterial, heat and posture in, 873  
high arterial, peripheral resistance in, [Prinzmetal] 742—ab  
high arterial, pressor substances in urine, [Capps] 159—ab  
high arterial, rôle of endocrine glands in pathogenesis, 868  
high, blood sugar in, 637  
high, classification on nitrogen distribution of serum proteins, [Rafsky] 1421—ab  
high, effect of hypertonic sucrose solution, [Murphy & others] 245—ab  
high essential, operations on sympathetic in, [Adson] \*364  
high essential, pregnancy in, [Albrecht] 425—ab  
high, eye changes in hypertensive toxemia of pregnancy, [Hallum] \*1619  
high, heart failure in, [Averbeck] 951  
high, hypertensive cerebral attack, [McAlpine] 500—ab  
high, hypertensive disease, 1839  
high, hypertensive disease, tests used in studying, 484, (correction) 635  
high, idiopathic, in pregnancy, 1029  
high, in diabetes, [Root] 1039—ab  
high, in thyrotoxicosis, [Maher & Sittler] \*1546  
high, irradiation of adrenals, etc. 294—E, [Hutton] 1040—ab; [Hutton & others] 1753—C, [Hogoff] 1753—C  
high malignant, [Derow] 162—ab  
high, potassium or sodium thiocyanate for, [Barker] \*762  
high, surgical treatment, [Adson] 1425—ab  
increase, in adrenal stimulation, [Kuré] 2204—ab  
intrapleural pressure (high) effect on, [Head] 159—ab  
 $\beta$  methyl  $\beta$ -methylamino- $\beta$ - $\gamma$ -heptene effect on, [Jackson] \*359  
pituitary pressor and oxytocic fractions effect on, [Melville] \*102  
pituitary rôle in regulation, [Kylin] 342—ab  
posture effect on tests for measuring, [Brown] \*354; \*356  
reactibility, cold pressor test for measuring, [Brown] \*354, \*355, [Hines] 951—ab  
sodium and potassium salts ingestion effect on, [McQuarrie] 1043—ab  
variability, [Hoverson] 1950—ab  
venous, effect of bath on, [Kruger] 753—ab  
venous (peripheral) in schizophrenic and in normal, [Krlnsky] 1125—ab
- BLOOD TRANSFUSION**, autotransfusion for wounds of heart, [Wiltor] \*520  
conserved blood for, [Filtor] 84—ab  
donor who has given 257 liters, 1507  
donors, opacitographic index for selecting, [Creswell & Wallace] \*1384  
donors, regulation, Vienna, 1934  
factors M and N in erythrocytes, [Blinov] 343—ab  
fractional, [Fonio] 2113—ab  
gallbladder contractility after, [Bettman & Tannenbaum] \*1376  
hemolytic shock after, 2241—E  
immunotransfusion in undulant fever, [Creswell & Wallace] \*1384  
in diptheria, [Seckel] 425—ab  
in empyema, [Schlegel] 1238—ab  
in internal diseases, [Blumberger] 584—ab  
in Italian Army, 309  
in puerperal infection, [Erbsloh] 1238—ab  
International Congress on (first), 309  
nephritis complicating, [Tzanek] 81—ab  
of cadaver blood, [Xudin] \*997  
protein reaction (nonspecific) after, [Filtor] 1771—ab  
syphilis transmitted by, [Mandelbaum & Sapirstein] \*1061  
uremia from, [DeGowin] 416—ab
- BLOOD VESSELS**: See also Arteries; Capillaries; Vasomotor Mechanism, Veins  
changes in legs, 1592  
disease, in obese diabetic, [Beck] 572—ab  
disease (obliterating) in aged, 646  
disease, Pavaex (passive exercise) treatment, [Conway] \*1153, [Wilso] & Roomel \*1885; [Council accepts] 1886  
disease, Pavaex (passive exercise unit) improved cuff for, [McKelvey] \*920  
disease, peripheral, operations on sympathetic in, [Adson] \*360  
disease, skin surface temperature as diagnostic method, [Bierman] \*1160  
disease, treatment by motorized oscillating bed, [Sanders] \*916  
Disorders. See Angioneurosis; Thromboangiitis obliterans; etc  
eclampsia and, [Irving] 1761—ab  
peripheral resistance in arterial hypertension, [Prinzmetal] 742—ab
- BLOODGOOD**, JOSEPH COLT, procedure for bone lesions, [Schrock] \*1884
- BLUM'S** Katcheln: See Thyroid, antithyroid substance  
**BOARD**, See American; National; Science Advisory Board  
Basic Science: See Medical Practice Acts; Medicolegal Abstracts at end of letter M  
**BODY** alcohol, carbon dioxide-oxygen inhalation to accelerate reduction, [Newman & Card] \*595  
Build: See Constitution  
Embalming: See Embalming  
Growth: See Growth  
Height: See Dwarfism; Giant  
surfaces relation to orientation of venous valves, [Edwards] 1638—ab  
Weight: See also Obesity  
weight loss during night, 239  
weight loss indicates surgical risk in peptic ulcer, [Studley] \*458  
weight, loss of, muscular tension when at rest, 1638—ab  
weight loss, prevention in psychoses, [Finkelmann] 156—ab
- BOECK** Sarcoid: See Sarcoid  
**BOIL**, See Abscess; Furunculosis; under Medicolegal Abstracts at end of letter M  
**BONDY** Mastoidectomy: See Mastoidectomy  
**BONE MARROW**: See also Myeloma; Sternum puncture  
changes in agranulocytosis, [Darling] 1037—ab  
culture; apparatus, [Osgood & Muscovitz] \*1888  
depression after neoparsphenamine, [Cowper] 1426—ab  
depression, clinical view, [Stevenson] 333—ab  
"maturation arrest," in granulocytopenia, [Dameshek] 2177—C  
reciprocal relation to myeloid and lymphoid tissues, [Wiseman & others] \*609  
red, distribution, [Huggins] 325—ab  
studies in infectious mononucleosis, [Freeman] 1947—ab
- BONES**. See also Cranium; Joints; Orthopedics, and under names of individual bones  
Abscess: See Arthritis; Tibia  
Ankylosis: See Temporomandibular Joint as human food, 769—ab  
atrophy, posttraumatic acute, [Gurd] 1126—ab  
Block Operation: See Foot drop  
Broken: See Fractures  
cancer metastasis from stomach, [Kerr] 249—ab  
cancer (metastatic), blood picture in, [Heck] 326—ab  
cancer (metastatic), large doses of calcium in, [Brunschwig] 737—ab  
cancer; sarcoma, pathologic fractures due to, [Welch] 1953—ab  
changes in march foot, [Maseritz] 656—ab  
cyst, malignant degeneration, [Francisco] 1851—ab  
deformed, in spite of vitamin D, 704—ab  
diet (restricted) effect on, 55  
Disease. See also Osteitis; Osteomyelitis disease and parathyroids, 1566—E  
disease, urinary calculi in, 469—E  
echinococcosis, diagnosis, [Ivanisovich] 1135  
forcess, fulcrum for, [Lusskin] \*918  
formation (heterotopic) from urinary tract epithelium, [Lucnesco] 2035—ab  
Fractures: See Fractures  
fragility, nature, [Puppel] 329—ab  
fragility, serum phosphatase in, [Smith] 329—ab  
graft eventually becomes rarefied, 392  
graft (massive onlay) of upper extremity, [West] 1130—ab  
graft to increase diameter of contracted pelvis, 2017  
Inflammations (late) of war, treatment, [Saroste] 580—ab  
lesions, Bloodgood's rules of procedure, [Schrock] \*1884  
softening, roentgen changes, [Camp] 2198—ab  
statistical data on human skeleton, 487  
tuberculosis, experimental, 1582  
tuberculosis, Gauvain's treatment, 1929  
tuberculosis, surgical treatment, 1215  
tumors, 138  
tumors, diagnostic difficulties; correlating societies for data on sarcoma, [Schrock] \*1882  
union, factors modifying, 485  
**BONNIE** Brand Hawaiian pineapple, 1387  
Farms Brand Evaporated Milk, 1899  
**BOOKS**: See also Bibliography; Library; Book Notices at end of letter B  
Carnation Cook Book, 1473  
exhibit (of old works, Bologna) 230; (of rare books, Australia) 554  
**BOOTH'S** Hyomel, 1111—BI  
**BORASH**, 143—BI  
**BORDEN'S** (evaporated milk), 293; (malted milk), 782  
**BORDEN** Memorial Lectureship established, 2164  
**BOTELHO'S** Reaction: See Uterus cancer  
**BOTRYOMYCOSIS**: See Granuloma pyogenicum  
**BOTULISM**: See also Food poisoning, Medicolegal Abstracts at end of letter M  
Botulinus Antitoxin, N.R.N., for prophylaxis and treatment, 1165

## C

- C.C.C. See Civilian Conservation Corps  
 CABOT, HUGH, "full steam" or caution in social security, 1737—E  
 CACHEXIA See Pituitary  
 CACODYLATE See Sodium  
 CADAVER blood, transfusion of, [Yudin] \*997  
 CAFFEINE See Coffee  
 CAISSON DISEASE, relation to tissue saturation with nitrogen, [Shilling] 163—ab  
 CALCIFICATION See also Calcinosi, Lymphatic System, Myositis  
 changes, 392  
 mechanism, rôle of phosphate ions in, 384—E  
 CALCINOSIS, cutaneous, [Costello] 498—ab  
 universal, [Ramsdell] 254—ab  
 CALCIUM, additive effect to digitals, 2 deaths [Bower & Menple] \*1151  
 chloride 10% Ampoule (Lakeside), 1008  
 Chloride Treatment See Gallbladder inflammation  
 concretions (spherical) in epididymis, [Mar-sella] 1047—ab  
 cyanamide in fertilizer, poisoning, rôle of alcohol, 237  
 deficiency disease in adult, [Haden] \*261  
 Gluconate, Ampoule Compound Solution U S S. P. Co., 1661  
 gluconate, Induced hypercalcemia, [Loven-burg & Ginsburg] \*1779  
 gluconate injections, effect on heart, [Ber-linger] 654—ab  
 in blood: See blood  
 in diet, effect on hypoparathyroidism, [Cazza-mali] 843—ab  
 in diet, relation to phosphorus, 2161—E  
 in diet; requirement of human adult, 2213—ab  
 Iodobehenate (Calloben or Sajodin), 239  
 metabolism and parathyroid surgery, [Mandl] 581—ab

## CALCIUM—Continued

- metabolism, influence of adrenals, [Schour] 1690—ab  
 phosphate-phosphoribital sedative, calcium with phenobarbital, [Robinson] 419—ab  
 Quinine Treatment See Pneumonia  
 Treatment See Bones, cancer, Colitis, ulcerative, Gallbladder inflammation  
 CALCULI See Biliary Tract, Gallbladder; Kidney, Urinary Tract  
 CALIFORNIA MEDICAL ASSOCIATION, resolution on diagnostic medical service, 1168  
 Ross-Loos case, 300  
 CALIOBEN See Calcium Iodobehenate  
 CALORIES, 2,000 needed per day, 1448—ab  
 CAMPHOR in 0.1 injection, eleomas and lipid necrosis after, [Repetto] 2203—ab  
 renohepatic degeneration from, 1750  
 CAMPS, diets for boys in, 2254  
 Work See Work camps  
 CANADIAN Medical Association, (Alberta Division) 133, (invitation to A. M. A.) 1819, 1907 1918, (Dr. Routley's address) 1907, (meeting) 1929  
 CANCER See also Adenocarcinoma, Chorion-epithelioma, Epithelioma Tumors, malignant, under specific organs as Breast; Uterus, etc., under Medicolegal Abstracts at end of letter M  
 Brazilian Congress of (first), 311, 1583  
 carcinogenic hydrocarbons, viscera tumors induced with, [Hfeld] 2101—ab  
 Cells See Lung cancer  
 clinics, Baltimore, 544  
 committee formed, Indiana, 1926  
 control program, (Kansas) 712, (Maine) 1576  
 diagnosis, Aron's adrenal cortex reaction, 1019  
 diagnosis, Botelho's seroreaction, 1583  
 diagnosis, group examinations, Germany, 638  
 diagnosis, Kauffmann's inflammatory reaction, [Ebbardt] 1135—ab  
 diagnosis, Schridde's cancer hair, [Frick] 1048—ab  
 diet and, 1902—E  
 etiology, estrogenic substance, 1093—E, [Cramer] 1768—ab  
 etiology, ultraviolet rays rôle in, [Roffo] 2111—ab  
 etiology, von Brehmer's Siphonospira polymorpha, 394  
 Experimental See Epithelioma  
 features, Lister Memorial Lecture by Muir, 2079  
 heredity and, [Little] \*2234  
 hospital, three million dollars for, New York, 1741  
 Imperial Cancer Research Fund, report, 716  
 in child aged 5 (of liver), 135  
 in slaughtered animals, 935  
 incidence in gastro-intestinal polyps, [Lawrence] 1420—ab  
 Koch Cancer Foundation loses malpractice suit, 929  
 metabolism rôle in, [Beard] 332—ab  
 metastases, preventing, by postoperative roentgen therapy, 1594  
 metastases to bone, blood picture in, [Heck] \*1975, [Heymann] \*2050  
 metastases to bone from breast, large doses of calcium in, [Brunschwig] 737—ab  
 metastases to bone from stomach, [Kerr] 249—ab  
 metastases to inguinal gland from penis, [Barringer] \*21  
 metastasis in lung cancer, [Arkin & Wagner] \*388  
 mortality, (Hungary) 1023 (Increase, California) 2011  
 Pain in See also Uterus cancer  
 pain in, cobra toxin for, [Nekula] 1239—ab  
 patients (improvised), financial aid for, 1404  
 phobia, glossodynia, [Gilpin] \*1722  
 "Research Aid Fund" of Maylar Greenfield, 864  
 scirrhus, diphtherial infection, [Marshall] 2108—ab  
 Serodiagnostics See Cancer, diagnosis  
 survey (Connecticut) 47 (Michigan) 130, (Illinois) 387  
 Treatment, Radium See Rectum, cancer, Tonsils, cancer, Uterus, cancer  
 Treatment, Roentgen See also Respiratory Tract cancer  
 treatment, roentgen (unfiltered), [Widmann] 330—ab, [Merritt] 2031—ab  
 treatment, short wave sensitization, [Fuchs] 2115—ab  
 trichinosis and, [Schmidt-Lange] 1433—ab  
 tuberculin reaction in, [Holmgren] 1434—ab  
 tuberculosis and, in alimentary canal, [Safwenberg] 968—ab  
 tuberculosis and, of bronchus, [Fleischner] 1861—ab  
 virus 717  
 CANDLE Jar Method See Carbon Dioxide  
 CANDY See also Chocolate  
 child's diet and, 1971—ab  
 CANKER Sores See Stomatitis  
 CANNED Food See Food  
 Milk See Milk  
 CAPILLARIES, Blood Pressure: See Blood Pressure  
 sure  
 breakdown, 148  
 resistance tests; vitamin C deficiency related to rheumatic fever, [Rinehart] 157—ab

## CAR: See Automobiles

- Sickness See Train sickness  
 CARBARSONE, toxicity, [Epstein] \*769  
 CARBOHYDRATES: See also Dextrose, Lactose; Sugar, etc.  
 diet (high) in chronic atrophic arthritis, [Bowen] 1233—ab  
 metabolism, effects of ingesting sodium and potassium salts, [McQuarrie] 1043—ab  
 metabolism in pneumonia, [Sinelnikor] 259—ab  
 CARBOLIC ACID: See Phenol  
 CARBON. See also Charcoal (cross reference)  
 Arc See Ultraviolet Rays  
 intravenously, granulotherapy, [Lumiere] 256—ab  
 Therapy. See Erysipelas  
 CARBON BISULFIDE poisoning, precautions against, 933  
 CARBON DIOXIDE, Absorption Technic See Anesthesia  
 mephitis, [Nye & Lamb] \*1075  
 Oxygen Inhalation: See Alcoholism  
 preservative of cod liver oil, Council state ment, 1733  
 preservative of fish, 470—E  
 snow treatment of angiooma and hemangioma, 561  
 CARBON MONOXIDE poisoning, headache in garage workers, 1332  
 poisoning, nervous and mental sequelae [Shillito & others] \*669  
 CARBON TETRACHLORIDE cirrhosis relation to liver regeneration, [Cameron] 1427—ab  
 poisoning, danger in removing adhesive tape 1755  
 poisoning, fatal inhalation of cleaning fluid [Gonzales] \*286  
 poisoning hazard in gasoline station attendant, 1409  
 CARBONIC ANHYDRASE in Blood See Blood  
 CARBUNCLE: See Kidney  
 CARCINOGENIC Hydrocarbons: See Cancer  
 CARCINOMA See Cancer  
 CARDIA. See under Stomach  
 CARDIODIAPHRAGMATIC Angina: See Angina Pectoris  
 CARDIOD Condenser: See Microscopy  
 CARDIOLOGY See Heart disease  
 CARDIOSPASM See Stomach  
 CARDIOVASCULAR DISEASE, syphilis and [Weber] 744—ab  
 syphilis, results of treatment, [Padgett] 569—ab  
 treatment by motorized oscillating bed, [Sanders] \*916  
 CARDIOVASCULAR SYSTEM status in thyrotoxicosis, [Maher & Sittler] \*1546  
 CRIES: See Spline  
 CARLSON, ANTON J., bust unveiled, 2074  
 CARNATION Company (Year Book of Menus and Recipes), 1009, (Cook Book) 1473, ("Simplified Infant Feeding") 1474  
 CAROTENE, absorption, [Heymann] 1419—ab  
 effect on diabetes mellitus, [Rall & others] \*1975, [Heymann] \*2050  
 CARPENTER, L. A., illegal practitioner, 2077  
 CARRIERS See Gonorrhea; Trichomonas, Typhoid  
 CARROTS, Cellu Brand, 1735  
 CARS See Automobiles  
 CARTILAGE See Meniscus, Rib  
 CASE HISTORY taking in allergic diseases, [Rackemann] \*976  
 CASEIN, allergy to, treatment, [Schloss & Anderson] 1025—C  
 production, industrial uses, 710—E  
 CASTELLANI, ALDO, in military service in Africa, 936  
 CASTLE'S Factors See Anemia, Pernicious  
 CASTOR OIL, place in diet, [McClendon] 64—C  
 used as laxative even in late pregnancy, 1591  
 used for hair dressing in asthmatic child 1839  
 CASTRATION, self-performed, [Frost & Gull] \*1708  
 unilateral, by x-rays, [Mouglano] 748—ab  
 voluntary, Germany, 2018  
 CATALASE, oxidizing ferments of raw vegetables and digestion, [Matveeff] 1134—16  
 Reaction See Feces  
 CATALOGUE See Index Catalogue  
 CATAPLEXY, post-traumatic, [Hall & LeRoy] \*431  
 CATARACT etiology, electric discharge, 66  
 extraction, frequency of retina detachment after, 1411  
 produced in rat by lactose or galactose, [Yudin] 496—ab  
 CATARRH See Sinuses, Nasal  
 CATATONIA See Dementia Praecox  
 CATGUT Sutures See Sutures  
 CATHTARIS See Castor Oil  
 CATTETER, Pezzar See Empyema  
 CATTLE See also Abortion, contagious  
 freemartin and intersexual, 1333  
 Tuberculosis in: See Tuberculosis, avian; Tuberculosis, bovine  
 CAUDA EQUINA, compression by ligamentum flavum [Abbott] \*2129  
 level of termination of spinal cord, [Needles] 496—ab  
 Neuritis See Neuritis  
 syndrome after subarachnoid alcohol injection, [Tureen & Gilt] \*1335  
 CAULIFLOWER, Cellu Brand, 1661

- CFCUM cancer, diagnostic criteria, [Rosser] \*109
- CELLS See also Cytology  
cytoplasmic inclusion bodies in throat, [Broadhurst] 1950—ab  
measurement of nuclei in tumors, [Schalrer] 425—ab
- CELLS (strawberries) 43; (red raspberries) 123, (black raspberries) 215, (prune plums) 467, (pineapple juice) 579, (spinach) 617, (tomatoes) 707, (mushrooms) 782, (yellow string beans) 923, (little lernel corn) 1166, (vegetable combination) 1187, (tips of asparagus) 1177, (green stringless beans) 1171, (tiny beets) 1565, (cauliflower) 1661; (carrots) 1735, (peas) 1809, (rhubarb) 1987

surgery, Plummer's iodine treatment before, [Melchior] 2115—ab  
treatment, roentgen, [Gunsett] 883—ab  
**GOLD**, colloidal, nostrum: Elorda Creams, 1678—BI  
preparations, fatal poisoning, [Fatzner] 1134—ab  
salts, relation to leukopenia, [Kracke] 1422—ab  
sphere, implantation in Tenon's space, 2181  
Treatment: See also Empyema, tuberculous; Lupus erythematosus; Tuberculosis, complications; Tuberculosis, Pulmonary  
treatment, pigmentation of skin after, [Cardis] 2203—ab  
**GOLDEN** Crest Brand Oleomargarine, 1987  
**GONADOTROPIC** PRINCIPLES: See also Pituitary, anterior; Pregnancy urine extract  
action on acid-base equilibrium disorders, [Bock] 582—ab  
function of pituitary in menopause, [Engelhart] 2116—ab  
treatment, effect of antuitrin-S on diabetes insipidus patient, [Allen & Stokes] \*780  
treatment of acne vulgaris with antuitrin-S, [Lawrence] \*983  
treatment of dysmenorrhea with antuitrin-S, [Israel] \*1698  
treatment of undescended testis, [Koplin] \*374; [Spence] 962—ab; [Allen & Stokes] \*780; [Dorff] 1111—C; 1507; [Werner & others] \*1541  
**GONADS**, biologic effects of pineal extract (Hanson), [Rowntree & others] \*370  
**GONIN** Procedure: See Retina detachment

## SUBJECT INDEX

2294

- GONOCOCCUS**, Committee for Survey of Research on, report, 1313—E  
Filtrate (Corbus-Ferry): See Gonorrhea diagnosis
- GONORRHEA**: See also Venereal Disease, under Medicolegal Abstracts at end of letter M  
admissions for; rates per population, Massachusetts, [Nelson] \*107  
Arthritis See Arthritis  
Bartholin gland abscess; question of carrier, 1593  
cause of sterility, 394  
chronic, granulations in urethra, 1116  
chronic; seasonal recurrence of urethral discharge, 1027  
Committee for Survey of Research on Gonococcus and Gonococcal Infections, report, 1313—E  
control, U. S. Public Health Service recommendation, [Vonderlehr & others] \*115  
diagnosis, 1939  
diagnosis, complement fixation test, [Hirshland] 1853—ab  
diagnosis, Koopman-Falkner complement fixation test, [Koopman] 958—ab  
diagnosis, skin reaction to Corbus-Ferry filtrate, 486, (clinical cure) [Corbus] 743—ab  
epithelial inclusions in women, [Spitzer] 83  
epithelial inclusions in women, [Spitzer] 83  
mask for early syphilis, [Kemp] 954—ab  
Ophthalmic See Ophthalmia  
phlebitis after, 617  
prostatitis, colitis during, 403  
septicemia with recovery, 56  
Serodiagnosis: See Gonorrhea diagnosis  
treatment, 2179  
treatment, basic fuchsin, [Araya] 2036—ab  
treatment, Corbus-Ferry filtrate, [Spence] 498—ab  
treatment, fever, [Desjardins & others] \*690  
treatment of acute gonorrheal urethritis in male and gonorrhea in women, 236  
treatment, phenylmercuric nitrate, [Biskind] 340—ab  
vaginitis, estrogenic substances for, [Lewis & Adler] \*2054
- GORDIUS robustus**, human parasitization, [Sayad & others] \*461
- GORDON Test**: See Lymphogranuloma
- Three Sevens (777)**, 143—B1
- GORRIE, JOHN**, father of artificial ice industry and air conditioning, 1939—E
- GOULD Negative Ion Process**, 706
- GOUT**, crampus neuroses and, [Vogl] 1137—ab  
pathogenesis, [Nishnevich] 1050—ab  
treatment, cinchophen, [Hench & others] 327—ab
- GRADUATE Courses**, Education See Education, Medical
- GRADUATES**, drug nihilism (practical factor), [David] \*405; [Schwartz] 871—C  
examined by licensing boards, \*1476—\*1478  
foreign, A. M. A. resolution on, 1912, 1921  
foreign, examined by state boards in U. S., \*1489—\*1491  
foreign, internships for, Council on Medical Education and Hospitals ruling, 1031  
foreign, licensing, Oregon state board ruling, 1505  
of other than approved medical schools registered, \*1485—\*1488; 1495—E
- GRAFT**: See Bones; Ovary; Skin
- GRANTS**: See American Medical Association, Foundation, Rockefeller, National Research Council
- GRANULOCYTOPENIA**. See Angina, agranulocytic
- GRANULOMA**: See also Lymphogranuloma  
annular, [Goodman] 1688—ab  
bacillary dysentery relation to, [Felsen] 2191—ab  
chronic ulcerating, maggot therapy, [Ayres] 740—ab  
coccioid, [Jordan] 740—ab  
coccioid, 11 drugs and vaccine for, [Sox & Dickson] \*777  
inguinal, stricture of rectum, 1838  
perigenital ulcerous, first case reported in Italy, 140  
pyogenicum, genital staphylococcal actinophytosis (Botryomycosis), [Berger] 1949—ab
- GRANULOPENIA**: See Angina, agranulocytic
- GRANULOTHERAPY**: See Carbon
- GRAPE JUICE**, Solitaire Brand, 1009
- GRAPEFRUIT**, brands accepted, 43; 293  
juice, brands accepted, 215; 333; 923; 1474; 1735
- GRAVITY**, Specific: See Urine
- GRAY'S Syrup**, 143—B1
- GREASE Paint**: See Cosmetics
- GREENFIELD, MAYLAR**, "Cancer Research Aid Fund," 864
- GREENS**: See Vegetables
- GRIDLEY Ice Cream**, 43
- GROVE'S Emulsified Nose Drops**, 1837—B1
- GROVE'S**: See also Dwarfism; Giant; Infants  
delayed, treatment, 2255  
effects of pinal extract (Hanson), [Rowntree & others] \*370
- GRUSKIN Test**: See Pregnancy, diagnosis
- GUMMA**: See Osteomyelitis
- GUMS**, periodontoclasia and gingivitis, [Healy] 2105—ab
- GUTTADIAPHOT Method**: See Blood
- GYNECOLOGY**, American Board of, examination results, 2078  
chronic mastitis and coincident lesions, [Taylor] 1045—ab  
Congress of German Society, 50th convention, 394  
National Congress of, A. M. A. resolution on, 1996, 1997  
New England Society, 1928
- GYNECOMASTIA**: See Breast
- GYNERGEN**: See Ergotamine tartrate
- GYPSIES**: See Gipsies
- H**
- HAEMOPHILUS pertussis**: See Whooping Cough
- HAIR**: See also Alopecia, Beard, Scalp  
Blond See Blondes  
hypertrophic, treatment, 563  
monilethrix, [Larsen] 1774—ab  
Oily See Scalp, oily  
pigmentation and copper, 629—E; [Alt] 1220—C  
Pulling Out: See Trichotillomania  
red haired people, skin infections in, 1756  
removal by irradiation, [Epstein] 1427—ab, [Symann] 1529—ab  
Schröder's cancer hair, [Frick] 1048—ab  
setting for asthmatic child, formula given, 1839  
washes, possible reaction from sodium sulfate, tartaric acid, 1224
- HALDANE, JOHN SCOTT**, death, 1671
- HALE'S Pride Brand grapefruit juice**; orange juice, 923
- HALIBUT LIVER OIL**, antioxidants (hydroquinone) as preservatives, Council statement, 1732  
Squibb Cod-Halibut Liver Oil, 214  
Treatment: See Sinusitis
- HAMBURGER Test**: See Tuberculin
- HAMMER Toe**: See Toes
- HANDEDNESS**: See Left Handedness
- HANDICAPPED Children**: See Children
- HANDS**, physically, WPA bureau for, 1577
- HANDS**: See also Fingers, Nails, Wrist  
injuries (industrial), 1676  
puscular bacteridia, [Andrews] 418—ab
- HANDWRITING** speed factor, classify school children by, [Quinn] 419—ab
- HANSON, J.**, 1510
- HANSON Pineal Extract**: See Pineal Gland
- HAPPY HOUR Brand Strained Vegetables**, 123
- HARDENER, Chrom-Alum**: See Chromium
- HARELIP**, hereditary nature, 58
- HARRISON NARCOTIC ACT**, physicians convicted continue in practice, 1819, 1915; 1916  
registration under, 1738—E
- HARTMAN'S SOLUTION**: See Teeth
- HARTMANN'S SOLUTION**, use of large volume intravenous injections, [Cutter] \*1250
- HARVARD** (course in automobile control) 712.  
(conference of arts and sciences) 1576;  
(symposium on atmospheric environment) 1670; (participates in tercentenary) 1926
- HASH**: See Beef
- HAWAIIAN Pineapple**: See Pineapple
- HAY, WILLIAM HOWARD**, letter from ex-patient, 63—B1
- HAY FEVER**, immunity, serologic evidence, [Cooke] 419—ab  
immunization, criticize Collins' use of term, [Berger] 483—1940  
pollen filtration, 1940  
pollen in Alpena, Mich. (reply) [Durham] 239  
pollen filtration, 1940  
treatment, ephedrine causes dermatitis of penis, [Hollander] \*706  
treatment, injecting specific oils unsuccessful, [Brunsing & Williams] \*1533  
treatment, ionization, [Ramirez] \*281; (reply) [Hays] 643—C, [Warwick] 939—C, (with zinc) 1116; [Bernheimer] \*1980
- HEAD**: See also Brain, Cranium, Hair, Hydrocephalus, Oxycephaly, Scalp  
injuries and temporal bone involvement, [Shoog] 1616—ab  
injuries, effects of cold applications (ice bag) on, 1113  
injuries (industrial), 1675  
injuries, management, [Money] 1046—ab
- HEADACHE**: See also Migraine  
carbon monoxide, in garage workers, 1332  
due to syphilis, 486  
menstruation and, 2091  
"splitting" at menopause, use of estrogenic substances in, 1599  
treatment, chondroitin, Council report, 293  
treatment, colon bacillus vaccine, [Mateer] 570—ab
- HEALING**: See Spine
- HEALTH**: See also Hygiene, Mental Hygiene;  
Sanitation  
albums (personal), system, Germany, 1831  
American Public Health Association, 1578  
Anti-Tobacco, Health Anti-Liquor, 2088—B1  
budget, protest curtailment, District of Columbia, 928  
Child: See Children  
city health contest, winner, 1670  
code, advisory board to formulate, U. S., 1929
